

## 1. BF7613BMXX-XJLX MCU General Description

### 1.1. Features

- **Core: 1T 8051**
- Operating frequency 12MHz, 6MHz, 4MHz, 1MHz
- Clock error: ±1% @ -20°C ~65°C, 5V  
±3% @-40°C ~105°C, 5V
- **Memory**
- FLASH: 32K bytes
- EEPROM: 2\*512 bytes
- SRAM: 256 bytes(data)+1024 bytes(xdata)
- Support 4K BOOT function
- **Clock source, reset**
- Internal low-speed clock LIRC: 32kHz  
Clock error: ±20% @25°C, 5V  
±35% @-40°C ~105°C, 5V
- Internal high-speed RC oscillator: 1MHz
- External crystal oscillator: 32768Hz
- 8 resets, including brown-out reset voltage 2.1V/  
2.8V/3.3V/3.7V/4.2V optional
- Low voltage detection:  
2.4V/2.7V/3.0V/3.3V/3.6V/3.9V/4.2V optional
- **IO**
- PB port built-in pull-up/pull-down resistor 33k, other  
IO ports built-in pull-up resistor 4.7k
- High current sink port (PB0~PB7)
- Support device peripheral function multiplexing
- All IO ports support external interrupt function,  
INT0~2 (rising-edge, falling-edge, double-edge), INT3  
shared interrupt source (rising-edge, falling-edge)
- **Communication Module**
- UART communication, support IO mapping
- IIC slave mode, support 100/400kHz
- **16-bit PWM**
- PWM0 supports multiple groups up to 4 channels,  
the same frequency, different duty cycle output
- PWM1/2 support up to 2 channels, the same  
frequency, different duty cycle output
- **Operating Voltage: 2.5 V ~ 5.5 V**
- **Operating Temperature: -40 °C ~ 105 °C**
- Enhanced industrial grade, in line with JESD  
industrial grade reliability certification standards
- **12-bit High-speed ADC**
- Up to 30 analog input channels
- Built-in reference voltage 4V
- **Interrupt**
- Two-level interrupt priority capability
- ADC, CSD, LED, INT0/1/2/3, LVDT, Timer0~2,  
WDT, UART0/1, IIC interrupt
- **Timer**
- 16-bit Timer0/1, 32-bit Timer2
- Timer2 clock source is internal low-speed clock  
LIRC 32k or XTAL 32768Hz
- Watchdog timer, overflow time 18ms to 2.304s
- **LED Driver**
- 4x4, 4x5, 5x6, 6x7, 7x7, 7x8, 8x8 dot matrix driver
- LED0~LED8 scan sequence is configurable
- **Low power mode**
- Idle mode and sleep mode
- Deep sleep, power consumption 3.5μA @5V typical
- **CTK**
- The key sensitivity is set independently
- Capacitive keys can be reused as GPIO
- **Two-wire programming, single-wire debugging  
simulation interface**
- **Package**
- SOP20/SOP28/TSSOP20/TSSOP28/  
LQFP32

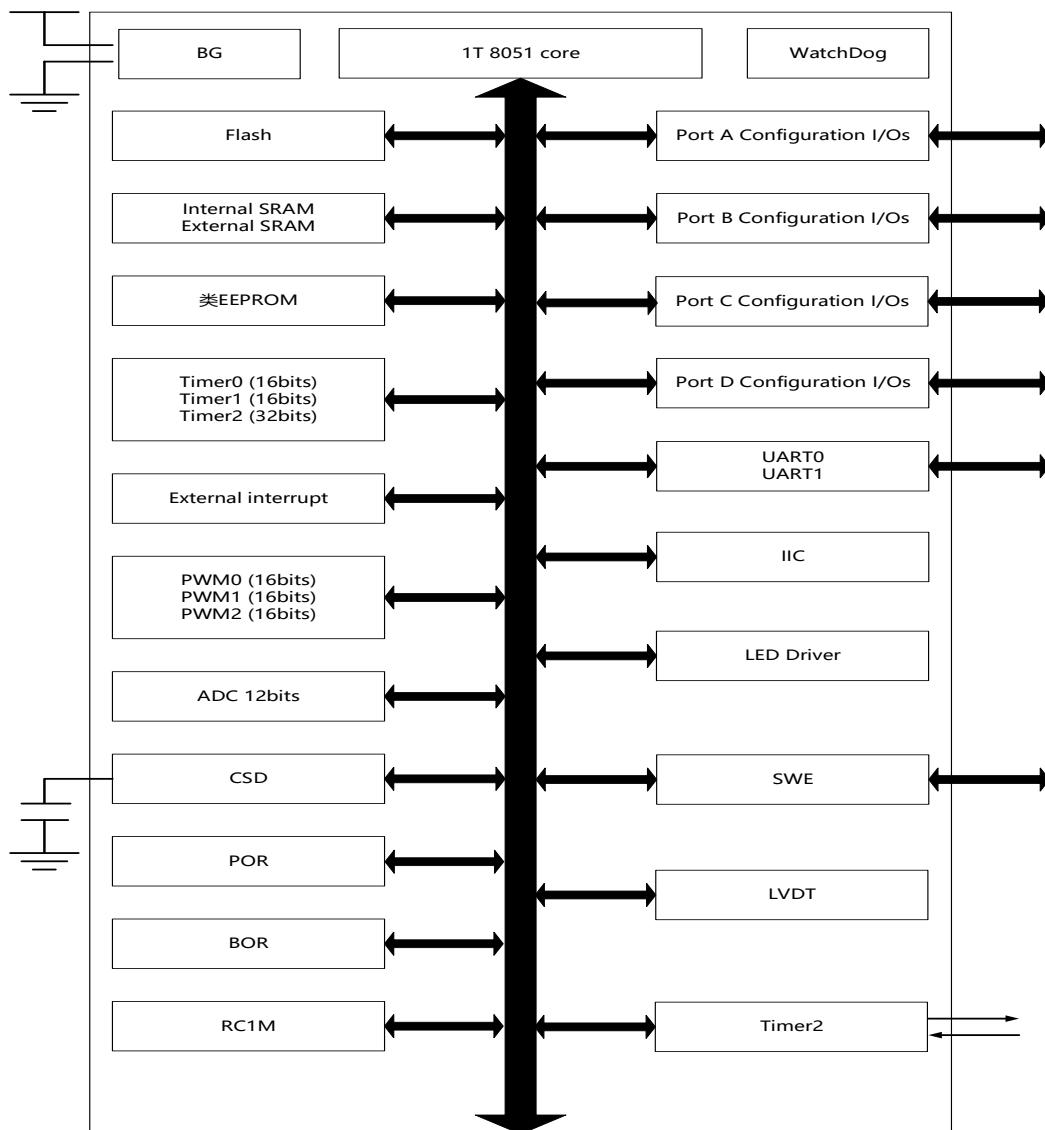

## 1.2. Overview

The BF7613BMXX-XJLX uses the high speed 8051 core with 1T instruction cycle, compared to the standard 8051 (12T) instruction cycle, has the quicker running speed, compatibility standard 8051 instruction.

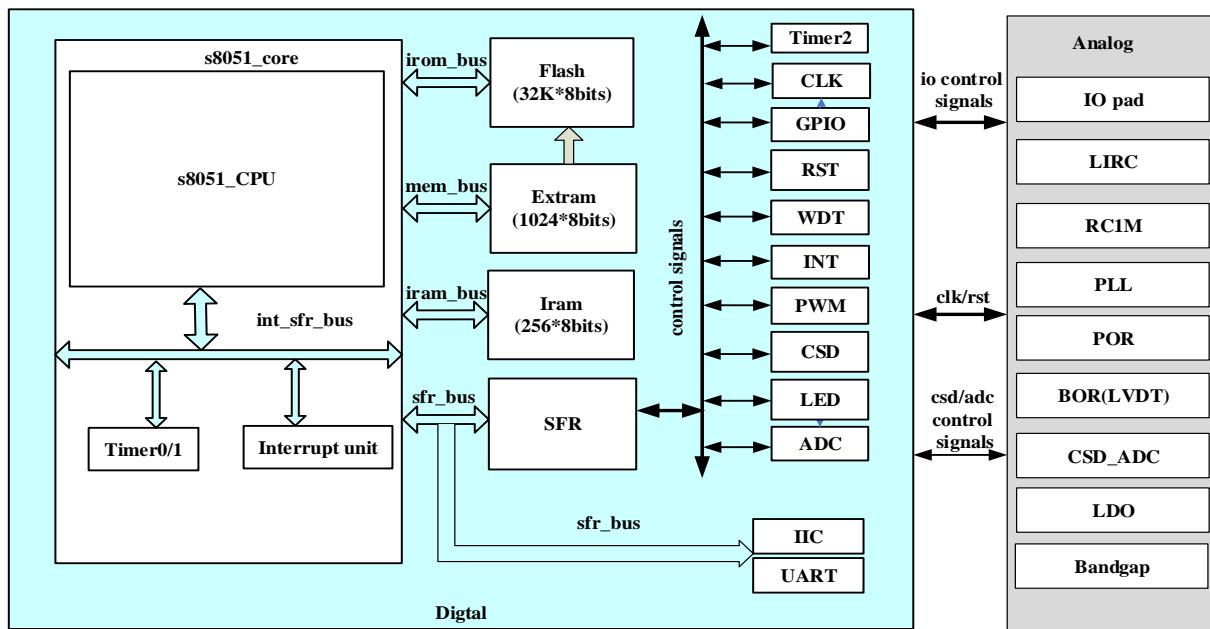

The BF7613BMXX-XJLX includes a watchdog, key detection, LED serial dot matrix driver, IIC, UART, low voltage detection, power down reset, 3-channel 16-bit PWM, Timer0, Timer1, Timer2, 12-bit successive approximation ADC, low power mode.

The BF7613BMXX-XJLX integrated capacitance channels, which can be used to detect proximity sensing or touch, its built-in MCU, can be flexible configurated, through the configuration can be implemented keys, rollers, sliders and other applications. A key can be run independently, and each key can be adjusted by corresponding special function registers to adjust the sensitivity.

### 3. RAM, FLASH and SFR

#### 3.1. Flash

Features:

- Main block 32KB, can be divided into 64 pages, each page is 512 B
- System block 512 B, information block 512 B
- EEPROM total 1K: NVR3 512 B, NVR4 512 B
- EEPROM supports page erasing and byte writing
- Program/erase times: Program area: at least 10000 times@25°C  
EEPROM: at least 100000 times@25°C
- Data retention: 100 years @25 °C  
20 years@85°C

Flash Storage Architecture

**Steps to read the unique identification code (UID) of the chip:**

1. Turn off the interrupt;
2. Read CODE absolute address 0x83A8~0x83B7 corresponding to product ID1~ID16;
3. Restore the interrupt setting.

**Steps to read Flash information:**

1. Turn off the interrupt;
2. Select the address to be read, and read the CODE absolute address;
3. Need to continue to read data, jump to step 2;
4. Restore interrupt settings.

### 3.2. RAM

There are 256 Bytes internal, the address is 00H~FFH, including working registers group, bit addressing areas, buffers and SFR, the buffer contain the stack area.

Internal low 128 Bytes, 00H~7FH has 128 Bytes. Read and write data by immediate addressing or indirect addressing.

Internal high 128 Bytes, 80H~FFH has 128 Bytes. Read and write data only by immediate addressing or indirect addressing.

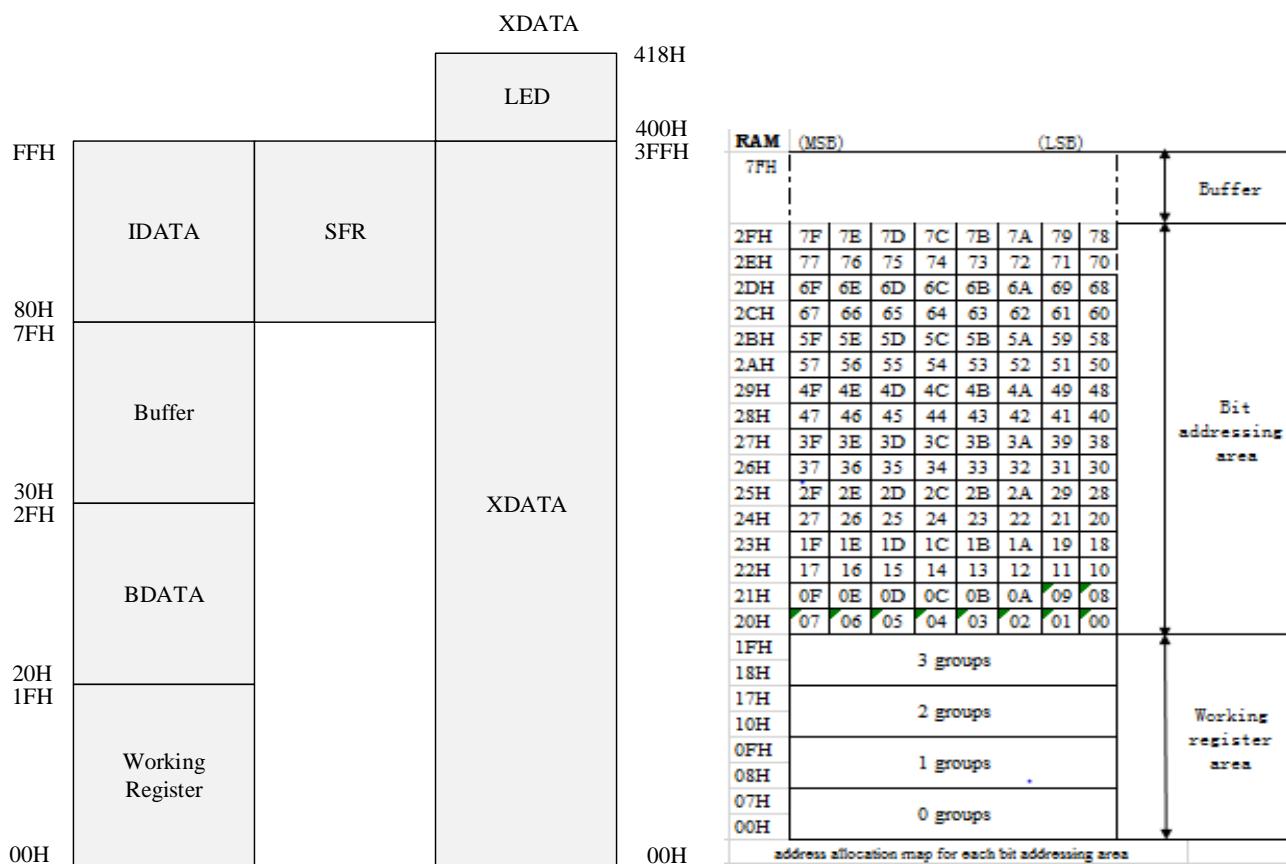

Special function register SFR: the address is 80H~FFH, Read and write data only by direct addressing.

Xdata has 1K Bytes, the address is 0000H~03FFH, users can use this area completely. To read and write data through the data pointer or working registers group addressing mode.

The LED storage RAM occupies the XRAM bus, the address is 400~418H.

Note reserved stack space when writing a program, in order to avoid stack overflow and program goes wrong. Stack first address automatically assigned by program, when programming with C language, but it must be stored in data or idata. KEIL stack can be set in the first address in STARTUP.A51.

RAM address space allocation map:

The following table lists the methods to get value in the three parts of RAM:

DATA	MOV A, direct MOV direct, A MOV direct, #data MOV direct1, direct2 MOV Rn, direct MOV direct, Rn
IDATA	MOV A, @Ri MOV @Ri, A MOV direct, @Ri MOV @Ri, direct MOV @Ri, #data
XDATA	MOVX @DPTR, A MOVX A, @DPTR

RAM value instruction set

**Notes:** n: 0~7, i: 0~1.

SFR register summary

**Note:** 1. Registers whose addresses end with 8 or 0 can be bit-operated, such as register

addresses 0x80, 0x88.

2. Reset value: reset value in different modes;

Power-on reset: rst\_state is 0x02;

Reset in other modes: The reset flag bit corresponding to rst\_state is 1, and other reset flags remain in their original state.

3. RO/R: only read. RW: read and write.

### 3.4. Secondary Bus Register Table

The BF7613BMXX-XJLX series supports expanded secondary bus registers for expanding more register functions. You only need to write the address of the secondary bus register to be accessed into REG\_ADDR, and then access the corresponding secondary bus register through the REG\_DATA register. It is recommended that when reading and writing secondary bus registers, first EA = 0, and then EA = 1 after the operation is completed. Prevent other interrupts or operations from modifying the address or data of the secondary bus register.

Addr	Name	Bit	R/W	Por	Function description
0x96	REG_ADDR	<5:0>	RW	0x00	Secondary bus address configuration register

0x2E	BOR_SEL	RW	state	BOR control register
0x2F	LVDT_SEL	RW	0x38	LVDT control register

Note:

1. The register whose address ends with 8 or 0 can be bit-operated.
2. Connect BOR\_SEL register to power-on reset: state is 0x18, other resets will not change the configuration value.
3. RO/R: Read only; RW: Read and write.

## 4. Register Summary

### 4.1. SFR Register Detailed Description

DATAB (80H) PB port data register

Bit number	7	6	5	4	3	2	1	0
Symbol	PB7	PB6	PB5	PB4	PB3	PB2	PB1	PB0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset value	1	1	1	1	1	1	1	1

Bit number	Bit symbol	Description
7~0	--	The output level of the PB group can be configured as the GPIO port. The read value is the level state of the current IO port or the configured output value.

SP (81H) Stack pointer register

Bit number	7	6	5	4	3	2	1	0
Symbol	SP[7:0]							
R/W	R/W							
Reset value	7							

DPL(82H) Data pointer register0 low 8-bit

Bit number	7	6	5	4	3	2	1	0
Symbol	DPL[7:0]							
R/W	R/W							
Reset value	0							

DPH (83H) Data pointer register0 high 8-bit

Bit number	7	6	5	4	3	2	1	0
Symbol	DPH[7:0]							
R/W	R/W							
Reset value	0							

SYS\_CLK\_CFG (84H) Clock control register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	WAIT_MODE	PLL_CLK_SEL	
R/W	-	-	-	-	-	R/W	R/W	
Reset value	-	-	-	-	-	0	0	1

Bit number	Bit symbol	Description
7~3	--	Reserved
2	WAIT_MODE	WAIT mode enable 1: The chip enters WAIT mode; 0: The chip exits WAIT mode
1~0	PLL_CLK_SEL	PLL clock divided selection register 00: 12MHz; 01: 6MHz; 10: 4MHz; 11: 1MHz

INT\_PE\_STAT(85H)WDT/Timer2 interrupt status register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	-	INT_WDT_STAT	INT_TIMER2_STAT
R/W	-	-	-	-	-	-	R/W	R/W
Reset value	-	-	-	-	-	-	0	0

Bit number	Bit symbol	Description
1	INT_WDT_STAT	WDT interrupt status, set 0, write WDT_CTRL can set 0. 1: interrupt effective 0: invalid interrupt
0	INT_TIMER2_STAT	TIMER2 interrupt status, set 0, write TIMER2_CFG can set 0. 1: interrupt effective 0: invalid interrupt

INT\_POBO\_STAT (86H) LVDT boost/LVDT buck interrupt status register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	-	INT_PO_STAT	INT_BO_STAT
R/W	-	-	-	-	-	-	R/W	R/W
Reset value	-	-	-	-	-	-	0	0

Bit number	Bit symbol	Description
1	INT_PO_STAT	Lvdt boost interrupt status 1: boost interrupt is valid 0: boost interrupt is invalid
0	INT_BO_STAT	Lvdt buck interrupt state 1: buck interrupt is valid 0: buck interrupt is invalid

PCON(87H) Low-power mode select register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	-		LPM
R/W	-	-	-	-	-	-	-	R/W
Reset value	-	-	-	-	-	-	-	0

Bit number	Bit symbol	Description
0	LPM	Low-power mode control 1: Low-power mode; 0: Normal mode, automatically cleared after wake-up

TCON(88H) Timer control register

Bit number	7	6	5	4	3	2	1	0
Symbol	TF1	TR1	TF0	TR0	IE1	-	IE0	-
R/W	R/W	R/W	R/W	R/W	R/W	-	R/W	-
Reset value	0	0	0	0	0	-	0	-

Bit number	Bit symbol	Description
7	TF1	Timer1 overflow flag. Set to 1 when Timer1 overflows, or Timer0's TH0 overflows in mode three.
6	TR1	Timer1 start enable. When set to 1, enable the Timer1 count or Timer0 TH0 count in mode 3.
5	TF0	Timer0 overflow flag. The hardware set 1 when Timer0 overflows.
4	TR0	Timer0 start enable, when set to 1, start Timer0 count.
3	IE1	External interrupt 1. The hardware set 1, the software is cleared.
1	IE0	External interrupt 0. The hardware set 1, the software is cleared
2, 0	--	Reserved

TMOD(89H) Timer mode register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	M1[1:0]		-	-	M0[1:0]	
R/W	-	-	R/W		-	-	R/W	
Reset value	-	-	0	0	-	-	0	0

Bit number	Bit symbol	Description
7~6, 3~2	--	Reserved
5~4	M1[1:0]	Timer1 mode select bits 00=mode0 – 13 bit Timer/counter 01=mode1 – 16 bit Timer/counter 10=mode2 – automatic reload mode 8bit counter 11=mode3 – 2*8bit counter
1~0	M0[1:0]	Timer0 mode select bits 00=mode0 – 13 bit Timer/counter

		01=mode1 – 16 bit Timer/counter 10=mode2 – automatic reload mode 8bit counter 11=mode3 – 2*8bit counter
--	--	---

TL0(8AH) Timer 0 counter 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	TL0[7:0]							
R/W	R/W							
Reset value	0							

TL1(8BH) Timer 1 counter low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	TL1[7:0]							
R/W	R/W							
Reset value	0							

TH0(8CH) Timer 0 counter high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	TH0[7:0]							
R/W	R/W							
Reset value	0							

TH1(8DH) Timer 1 counter high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	TH1[7:0]							
R/W	R/W							
Reset value	0							

SOFT\_RST(8EH) Soft reset register

Bit number	7	6	5	4	3	2	1	0
Symbol	-							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	--	Software reset register. Software reset is only generated when the register value is 0x55.

DATAC(90H) PC port data register

Bit number	7	6	5	4	3	2	1	0
Symbol	PC7	PC6	PC5	PC4	PC3	PC2	PC1	PC0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset value	1	1	1	1	1	1	1	1

Bit number	Bit symbol	Description
7~0	--	PC data register. The output level of the PC group can be configured as the GPIO port. The read value is the level state of the current IO port or the configured output value.

WDT\_CTRL(91H) WDT timing overflow control register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	WDT_TIME_SEL		
R/W	-	-	-	-	-	R/W		
Reset value	-	-	-	-	-	0	0	0

Bit number	Bit symbol	Description
7~0	WDT_TIME_SEL	WDT overflow timer register. Timing length is as follows: 0x00: 18ms; 0x01: 36ms; 0x02: 72ms; 0x03: 144ms; 0x04: 288ms; 0x05: 576ms; 0x06: 1152ms; 0x07: 2304ms;

WDT\_EN(92H) WDT timing enable register

Bit number	7	6	5	4	3	2	1	0
Symbol								WDT_EN
R/W								R/W
Reset value								0

Bit number	Bit symbol	Description
7~0	WDT_EN	WDT timing enable configuration register. WDT is turned off when the configuration value is 0x55.

TIMER2\_CFG (93H) TIMER2 CFG register

Bit number	7~4	3	2	1	0
Symbol	-	TIMER2_CNT_MOD	TIMER2_CLK_SEL	TIMER2_RLD	TIMER2_EN
R/W	-	R/W	R/W	R/W	R/W
Reset value	-	0	0	0	0

Bit number	Bit symbol	Description
3	TIMER2_CNT_MOD	TIMER2 count step mode select register 1: count step is 65536 clock. 0: count step is 1 clock.
2	TIMER2_CLK_SEL	TIMER2 clock select register 1: select XTAL32768Hz 0: select LIRC
1	TIMER2_RLD	TIMER2 reload enable control register 1: automatic reload mode

		0: manual reload mode
0	TIMER2_EN	<p>TIMER2 count enable register            1: turn on timing;            0: stop timing;</p> <p>In manual reload mode, the hardware automatically clears this register after timing is completed, stop count.            In manual reload mode, will maintain the enable register after the count is completed. Automatically re-counting from 0, no matter which mode, configuring this register to 1 during counting will start counting from 0.</p>

**TIMER2\_SET\_H(94H) TIMER2 count value configuration register, high 8 bits**

Bit number	7	6	5	4	3	2	1	0
Symbol							-	
R/W							R/W	
Reset value							0	

Bit number	Bit symbol	Description
7~0	--	TIMER2 count configuration register, high 8 bits. Configuring this register during the scan will recount.

**TIMER2\_SET\_L(95H) TIMER2 count value configuration register, low 8 bits**

Bit number	7	6	5	4	3	2	1	0
Symbol							-	
R/W							R/W	
Reset value							0	

Bit number	Bit symbol	Description
7~0	--	TIMER2 count configuration register, low 8 bits. Configuring this register during the scan will recount.

**DATAD(98H) PD port data register**

Bit number	7	6	5	4	3	2	1	0
Symbol	PD7	PD6	PD5	PD4	PD3	PD2	PD1	PD0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset value	1	1	1	1	1	1	1	1

Bit number	Bit symbol	Description
7~0	--	PD data register. The output level of the PD group can be configured as the GPIO port. The read value is the level state of the current IO port or the configured output value.

PWM1\_CH0\_CNT\_L (99H) PWM1 channel 0 count value configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM1_CH0_CNT_L							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM1_CH0_CNT_L	PWM1 channel 0 count value configuration register low 8 bits. Configure the PWM output duty cycle

PWM1\_CH0\_CNT\_H (9AH) PWM1 channel 0 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM1_CH0_CNT_H							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM1_CH0_CNT_H	PWM1 channel 0 count value configuration register high 8 bits. Configure the PWM output duty cycle

PWM1\_CH1\_CNT\_L (9BH) PWM1 channel 1 count value configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM1_CH1_CNT_L							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM1_CH1_CNT_L	PWM1 channel 1 count value configuration register low 8 bits. Configure the PWM output duty cycle

PWM1\_CH1\_CNT\_H (9CH) PWM1 channel 1 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM1_CH1_CNT_H							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM1_CH1_CNT_H	PWM1 channel 1 count value configuration register high 8 bits. Configure the PWM output duty cycle

PWM2\_CH0\_CNT\_L (9DH) PWM2 channel 0 count value configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM2_CH0_CNT_L							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM2_CH0_CNT_L	PWM2 channel 0 count value configuration register low 8 bits. Configure the PWM output duty cycle

PWM2\_CH0\_CNT\_H (9EH) PWM2 channel 0 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM2_CH0_CNT_H							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM2_CH0_CNT_H	PWM2 channel 0 count value configuration register high 8 bits. Configure the PWM output duty cycle

PWM2\_CH1\_CNT\_L (9FH) PWM2 channel 1 count value configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM2_CH1_CNT_L							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM2_CH1_CNT_L	PWM2 channel 1 count value configuration register low 8 bits. Configure the PWM output duty cycle

P2\_XH (A0H) MOVX @Ri,A operation xdata address high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	-							
R/W	R/W							
Reset value	FF							

Bit number	Bit symbol	Description
7~0	P2_XH	When using the MOVX @Ri, A instruction, when operating the pdata area, P2_XH need to be clear to 0.

PWM2\_CH1\_CNT\_H (A1H) PWM2 channel 1 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM2_CH1_CNT_H							

R/W	R/W
Reset value	0

Bit number	Bit symbol	Description
7~0	PWM2_CH1_CNT_H	PWM2 channel 1 count value configuration register high 8 bits. Configure the PWM output duty cycle

PWM\_EN (A2H) PWM control register

Bit number	7	6	5	4
Symbol	PWM2_CH1_CMOD	PWM1_CH1_CMOD	PWM0_CH3_CMOD	PWM0_CH2_CMOD
R/W	R/W	R/W	R/W	R/W

2	PWM0_CH2_EN	Channel 2 enable ch2_en 1: enable 0: not enable
1	PWM0_CH1_EN	Channel 1 enable ch1_en 1: enable 0: not enable
0	PWM0_CH0_EN	Channel 0 enable ch0_en 1: enable 0: not enable

PWM0\_CH0\_CNT\_L (A4H) PWM0 channel 0 count value configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_CH0_CNT_L							

R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_CH0_CNT_L	Channel 0 count configuration register low 8 bits. Configure PWM output duty cycle.

PWM0\_CH0\_CNT\_H (A5H) PWM0 channel 0 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_CH0_CNT_H							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_CH0_CNT_H	Channel 0 count configuration register high 8 bits. Configure PWM output duty cycle.

PWM0\_CH1\_CNT\_L (A6H) PWM0 channel 1 count value configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_CH1_CNT_L							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_CH1_CNT_L	Channel 1 count configuration register low 8 bits. Configure PWM output duty cycle.

PWM0\_CH1\_CNT\_H (A7H) PWM0 channel 1 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_CH1_CNT_H							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_CH1_CNT_H	Channel 1 count configuration register high 8 bits. Configure PWM output duty cycle.

IEN0(A8H) Interrupt enable register

Bit number	7	6	5	4	3	2	1	0
Symbol	EA	-	-	-	ET1	EX1	ET0	EX0
R/W	R/W	-	-	-	R/W	R/W	R/W	R/W
Reset value	0	-	-	-	0	0	0	0

Bit number	Bit symbol	Description
7	EA	Interrupt enable bit 0: Mask all interrupts (EA has priority over the respective interrupt enable bits of the interrupt sources); 1: The interrupt is turned on. Whether the interrupt request of each interrupt source is allowed or forbidden is determined by the respective enable bit.
6~4	--	Reserved
3	ET1	Timer1 interrupt enable bit 0: Disable timer 1 to apply for interrupt; 1: Allow timer 1 flag bit to apply for interrupt.
2	EX1	INT_EXT1 enable bit 0: Disable INT_EXT1 to apply for interrupt; 1: Allow INT_EXT1 to apply for interrupt.
1	ET0	Timer 0 interrupt enable bit 0: Disable timer 0 (TF0) to apply for interrupt; 1: Allow TF0 flag bit to request interrupt.
0	EX0	INT_EXT0 enable bit 0: Disable INT_EXT0 to apply for interrupt; 1: Allow INT_EXT0 to apply for interrupt.

PWM0\_CH2\_CNT\_L (A9H) PWM0 channel 2 count value configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_CH2_CNT_L							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_CH2_CNT_L	Channel 2 count configuration register low 8 bits. Configure PWM output duty cycle.

PWM0\_CH2\_CNT\_H (AAH) PWM0 channel 2 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0

7~0	PWM0_CH3_CNT_L	Channel 3 count configuration register low 8 bits. Configure PWM output duty cycle.

PWM0\_CH3\_CNT\_H (ACH) PWM0 channel 3 count value configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_CH3_CNT_H							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_CH3_CNT_H	Channel 3 count configuration register low 8 bits. Configure PWM output duty cycle.

PWM0\_MOD\_L (ADH) PWM0 cycle configuration register low 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_MOD_L							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_MOD_L	PWM0 count cycle configuration register low 8 bits. Configure PWM output duty cycle.

PWM0\_MOD\_H (AEH) PWM0 cycle configuration register high 8 bits

Bit number	7	6	5	4	3	2	1	0
Symbol	PWM0_MOD_H							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	PWM0_MOD_H	PWM0 count cycle configuration register high 8 bits. Configure PWM output duty cycle.

SCAN\_START(AFH) LED scan open register

Bit number	7	6	5	4	3	2	1	0
Symbol	-							
R/W	-							
Reset value	-							

Bit number	Bit symbol	Description
0	--	LED scan on register 1: Scan on; 0: Scan off

DP\_CON (B0H) LED scan control register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	DUTY_SEL			SCAN_MODE	COM_MOD
R/W	-	-	-	R/W			R/W	R/W
Reset value	-	-	-	0	0	0	0	0

Bit number	Bit symbol	Description
4~2	DUTY_SEL	LED port drive mode matrix selection configuration register 0: no matrix; 1: 4x4 matrix; 2: 4x5 matrix; 3: 5x6 matrix; 4: 6x7 matrix; 5: 7x7 matrix; 6: 7x8 matrix; 7: 8x8 matrix
1	SCAN_MODE	LED scan mode. 1: cycle scan mode 0: interrupt scan mode
0	COM_MOD	Large sink current ports drive enable. 1: COM port function lock, work as a large current IO port. 0: COM port function is not locked and can be configured as other functions.  When the COM port locks the large sink current IO port, by configuring GPIO registers output drive timing, it is valid when all of the following LED scan configurations are invalid.

SCAN\_WIDTH (B1H) LED scan on time 1 control register

Bit number	7	6	5	4	3	2	1	0
Symbol						-		
R/W						R/W		
Reset value						0		

Bit number	Bit symbol	Description
7~0	--	In the LED dot matrix drive mode, the corresponding single lamp lighting time configuration register-the first segment of lamp cycle configuration period=(scan_width+1)*16us, support configuration range 0.016~4.096ms

**LED2\_WIDTH (B2H) LED scan on time 2 control register**

Bit number	7	6	5	4	3	2	1	0
Symbol					-			
R/W					R/W			
Reset value					0			

Bit number	Bit symbol	Description
7~0	--	In the LED dot matrix drive mode, the corresponding single lamp lighting time configuration register-the second stage of lamp cycle configuration period=(led2_width+1)*16us, support configuration range 0.016~4.096ms

**LED2\_DRIVE (B3H) LED drive capability configuration register**

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-			-	
R/W	-	-	-	-			R/W	
Reset value	-	-	-	-			0	

Bit number	Bit symbol	Description
3~0	-	LED port drive capability configuration register 0~15—4mA~72mA, please refer to LED drive ammeter for details.

**ADC\_SPT (B4H) ADC sample time configure register**

Bit number	7	6	5	4	3	2	1	0
Symbol					ADC_SPT			
R/W					R/W			
Reset value					0			

Bit number	Bit symbol	Description
7~0	ADC_SPT	ADC sample time configure register sample time: sample_Timer = (ADC_SPT+1)*4Tadc_clk

**ADC\_SCAN\_CFG (B5H) ADC scan control register**

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	ADC_ADDR					ADC_START
R/W	-	-	R/W					R/W
Reset value	-	-	0					0

Bit number	Bit symbol	Description
5~1	ADC_ADDR	ADC channel address selection register 00000: corresponds to ADC0; 00001: corresponding to ADC1; ... 11100: corresponding to ADC28; 11101: corresponding to ADC29; 11110: ADC30_VREF; 11111: reserved
0	ADC_START	ADC scan enable register 0: ADC module does not scan; 1: ADC module starts scanning ADC_START is set from 0 to 1, ADC starts to scan, after scanning once, ADC_START hardware is automatically set to 0, corresponding to the ADC interrupt flag bit, the ADC interrupt flag bit needs to be cleared by software Note: ADC_START is not allowed to be configured during scanning

**ADCCCKC (B6H) ADC clock control register**

Bit number	7	6	5	4	3	2	1	0

Reset value	0	0	0	0

Bit number	Bit symbol	Description
6	UART0_R8	Receiver's ninth data, read only.
5	UART0_T8	Transmitter's ninth data, read only when parity is enabled.
4	TI0	Send interrupt flag. 1: send buffer is empty; 0: send buffer is full, software write 0 clear 0, write 1 invalid.
3	RI0	Receive interrupt flag. 1: receive buffer is full; 0: receive buffer is empty, software write 0 clear 0, write 1 invalid.
2	UART0_RO	Receive overflow flag; 1: receive overflow (lost new data); 0: no overflow, software write 0 clear 0, write 1 invalid.
1	UART0_F	Framing error flag. 1: framing error flag;

		0: no framing error flag, software write 0 clear 0, write 1 invalid.
0	UART0_P	Parity error flag. 1: receiver parity error; 0: parity is correct, software write 0 clear 0, write 1 invalid.

UART0\_BUF (C1H) UART0 data register

Bit number	7	6	5	4	3	2	1	0
Symbol					-			
R/W					R/W			
Reset value					FF			

Bit number	Bit symbol	Description
7~0	--	Data register Read returns read-only receive data buffer contents, write into write-only send data buffer.

5	UART1_T8	The 9th data of the transmitter, read only during parity check
4	TI1	Send buffer empty interrupt flag 1: The sending buffer is empty; 0: Send buffer is full, software write 0 to clear
3	RI1	Receive interrupt flag 1: The receive buffer is full; 0: Receive buffer is empty, software write 0 to clear
2	UART1_RO	Receive overflow flag 1: Receive overflow (new data is lost); 0: No overflow, software writes 0 to clear
1	UART1_F	Frame error flag 1: A frame error is detected; 0: No frame error is detected, software writes 0 to clear
0	UART1_P	Parity error flag 1: Receiver parity error; 0: Parity check is correct, software writes 0 to clear

UART1\_BUF (C9H) UART1 data register

Bit number	7	6	5	4	3	2	1	0
Symbol					-			
R/W					R/W			
Reset value					FF			

Bit number	Bit symbol	Description
7~0	-	Read returns the contents of the read-only receive data buffer, writes to the write-only send data buffer.

CSD\_START(CAH) CSD scan open register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	-	-	-
R/W	-	-	-	-	-	-	-	R/W
Reset value	-	-	-	-	-	-	-	0

Bit number	Bit symbol	Description
0	-	1: CSD scanning is on; 0: CSD scan stops Write 1 in CSD_START to start scanning. After one scan, the hardware will automatically set to 0. If you want to start the next scan, you need to set it to 1 again by software; if

		CSD_START=0 during the scan, the scan will stop immediately, and the module will have related internal signals Reset  Note: Must be used in accordance with the process configuration: CSD_START=1, if interruption is detected, configure CSD_START=0. CSD_START is not allowed to be configured during scanning

R/W	R/W	R/W	R/W	R/W		R/W	R/W	R/W
Reset value	0	0	0	0	0	0	0	0

Bit number	Bit symbol	Description
7	CY	Carry flag. Set when the addition generates a carry or subtracts a borrow, otherwise clears. Set when the first operand of CJNE is less than the second operand, cleared by MUL or DIV instruction. Also affected by mouse commands (RLC, RRC) and bitwise

		instructions.
6	AC	Auxiliary carry flag Set when the addition is borrowed from the third to fourth bits of the accumulator, or when the subtraction is borrowed from the third to fourth bits, otherwise cleared.
5	F0	0 flag bit. Universal label for users.
4~3	RS[1:0]	Working register group: Select a valid working register group: RS[1:0] Bank IRAM Area 00 0 0x00-0x07; 01 1 0x08-0x0F; 10 2 0x10-0x17; 11 3 0x18-0x1F
2	OV	Overflow flag bit When the addition produces a different carry of accumulator bits 6 and 7, or subtraction produces a borrow of accumulator bits 6 and 7, otherwise cleared. The OV flag indicates that the signed 8-bit result is out of bounds (greater than 127 or less than -128). The overflow flag is also set when the multiplication result is greater than 255 or an attempt is made to divide by 0.
1	F1	1 flag bit. Universal label for users.
0	P	Parity flag. Always contains the sum of Form 2 of all the bits in the accumulator.

PULL\_I\_SELA\_L (D1H) CSD pull-up current source selection register

Bit number	7	6	5	4	3	2	1	0
Symbol	PULL_I_SEL<7:0>

1	PD_CSD	Analog CSD work control register: 0: CSD module works normally; 1: CSD module does not work
0	PD_ADC	Analog ADC shutdown control register 0: ADC module works normally; 1: ADC module does not work

Note:

1. Reset value: reset value in different modes;

RST\_STAT register power-on reset: rst\_state is 0x02;

Reset in other modes: the reset flag bit corresponding to rst\_state is 1, and other reset flags remain in their original state;

2. The reserved register and the reserved bits of the register are forbidden to write operation, otherwise the chip may be abnormal.

## 4.2. Secondary Bus Registers Detailed Description

CFG0\_REG (00H) Configuration word register 0

Bit number	7	6	5	4	3	2	1	0
Symbol					-

Note: In this mode, SPROG_ADDR_H, SPROG_ADDR_L, SPROG_DATA, SPROG_CMD, SPROG_TIM are reused as the BOOT upgrade function. {SPROG_ADDR_H, SPROG_ADDR_L} are multiplexed into all Flash space addresses from 0x0000 to 0x7FFF.

BOOT\_CMD (22H) Program space jump instruction register

Bit number	7	6	5	4	3	2	1	0
Symbol	-							
R/W	RW							
Reset value	0							

Bit number	Bit symbol	Description
7~0	--	Configure the program space jump instruction, write 5 groups of data (0xFF, 0x00, 0x88, 0x55, 0xAA) continuously, and jump into the main program space; Continuously write 5 groups of data (0x37, 0xC8, 0x42, 0x9A, 0x65), jump into the Boot program space; the value read out is the most recently written byte.

ROM\_OFFSET\_L (23H) Address offset of CODE area (low 8 bits)

Bit number	7	6	5	4	3	2	1	0
Symbol	-							
R/W	RO							
Reset value	0							

Bit number	Bit symbol	Description

**ADC\_CFG1(25H) ADC configuration register**

Bit number	7	6	5	4	3	2	1	0
Symbol	-	ADCWNUM						ADC_I_SEL
R/W	-	RW	RW	RW	RW	RW	RW	RW
Reset value	-	0	0	0	0	0	0	0

Bit number	Bit symbol	Description
6~2	ADCWNUM	Selection of distance conversion interval after sampling: 3+ADCWNUM(ADC_CLK)
1	ADC_I_SEL[1]	ADC selects comparator bias current 1: 4uA; 0: 5uA
0	ADC_I_SEL[0]	ADC selects BUFFER bias current 1: 4uA; 0: 5uA

**ADC\_CFG2 (26H) ADC comparator offset cancellation selection register**

Bit number	7	6	5	4
Symbol	-	-	ADC_VREF_SEL	ADC_VREF_VOL_SEL
R/W	-	-	RW	RW
Reset value	-	-	0	0
Bit number	3	2	1	0
Symbol	VREF_IN_ADC_SEL		CTRL_SEL	
R/W	RW	RW	RW	RW
Reset value	0	0	1	0

Bit number	Bit symbol	Description
5	ADC_VREF_SEL	ADC reference voltage selection: 0: select VCC as the output signal; 1:select the voltage output by the ADC_VREF module as the reference voltage
4	ADC_VREF_VOL_SEL	ADC_VREF output mode selection: 0: reserved; 1: 4V as ADC reference voltage When the ADC_VREF output mode selects 4V as the ADC reference voltage, it is recommended to use 3MHz for the ADC frequency division clock
3~2	VREF_IN_ADC_SEL	Voltage selection input to the internal ADC channel of the chip 00: 1.362V; 01: 2.253V; 10: 3.111V; 11: 4.082V;
1~0	CTRL_SEL	ADC offset cancellation timing selection, the default value is 10 00/01: firstly eliminate the offset and then sample; 10/11: Offset elimination and sampling are performed simultaneously. 10: The switch of the first-level comparator is finally disconnected; 11: All switches are disconnected at the same time

**PERIPH\_IO\_SEL 4(27H) INT3 select enable register 4**

2~0	SEL_LVDT_VTH	LVDT threshold selection

## 5. Clock, Reset, Work Mode, WDT

### 5.1. Clock Definition

Clock block diagram

The BF7613BMXX-XJLX series clock is defined as follows:

**XTAL32768Hz:** external 32768 Hz precision clock, which can be used as Timer2 clock.

**RC1MHz:** built-in RC oscillator with a frequency of 1MHz.

**LIRC:** internal low-speed clock, this clock is used as watchdog clock and Timer2 clock.

**PLL\_24MHz:** frequency 24MHz, gate control module enabled, used as UART, Flash control, clock source and system clock after frequency division.

**PLL\_48MHz:** The frequency is 48MHz, the gating module is enabled, and it is used as the CSD and ADC clock source.

**SCL:** IIC master clock, sent by the IIC Master, as the IIC communication clock.

**PGC:** Programming clock, download clock when programming and burning programs.

### 5.3. Reset

There are 8 reset modes in BF7613BMXX-XJLX: WDT overflow reset (WDTRST\_F), power on reset (PO\_F), brown-out reset (BO\_F), program reset (PROG\_F), debug reset (DEBUG\_F), PC pointer overflow reset (ADDROF\_F), software reset (SOFT\_F), IAP operation BOOT upgrade reset (BOOT\_F). Any one of above reset, global will make chip reset. We can judge the reset flag register which reset happen, the reset must be cleared by software.

## Reset block diagram

### 5.3.1. Reset Sequence

**po\_n**: Power-on reset. After the system is powered on, the analog module generates a low-level signal and lasts for 93ms. When the power-on reset is low, the entire chip is in the reset state, and after the global reset signal continues to be effective 20ms after the power-on reset is high, the system exits the reset mode.

**bo\_n**: Brown-out reset, the analog module generates a low-level signal after the system has a power-down reset. When the power-down reset signal is low, the entire chip is in the reset state. After the global reset signal becomes high, the system exits the reset mode after the global reset signal continues to be valid for 20ms.

**prog\_en:** Programming reset. When prog\_en is high, it is the programming mode of FLASH. At this time, the global reset signal is valid. After it goes low, the global reset signal continues to be valid for 20ms.

**soft\_rst:** software reset, the soft reset signal is valid by writing SFR, and the global reset signal is valid for 20ms. After 20ms, the system exits the reset mode.

**prog\_en:** Programming reset. When prog\_en is high, it is the programming mode of FLASH. At this time, the global reset signal is valid. After it goes low, the global reset signal continues to be valid for 20ms.

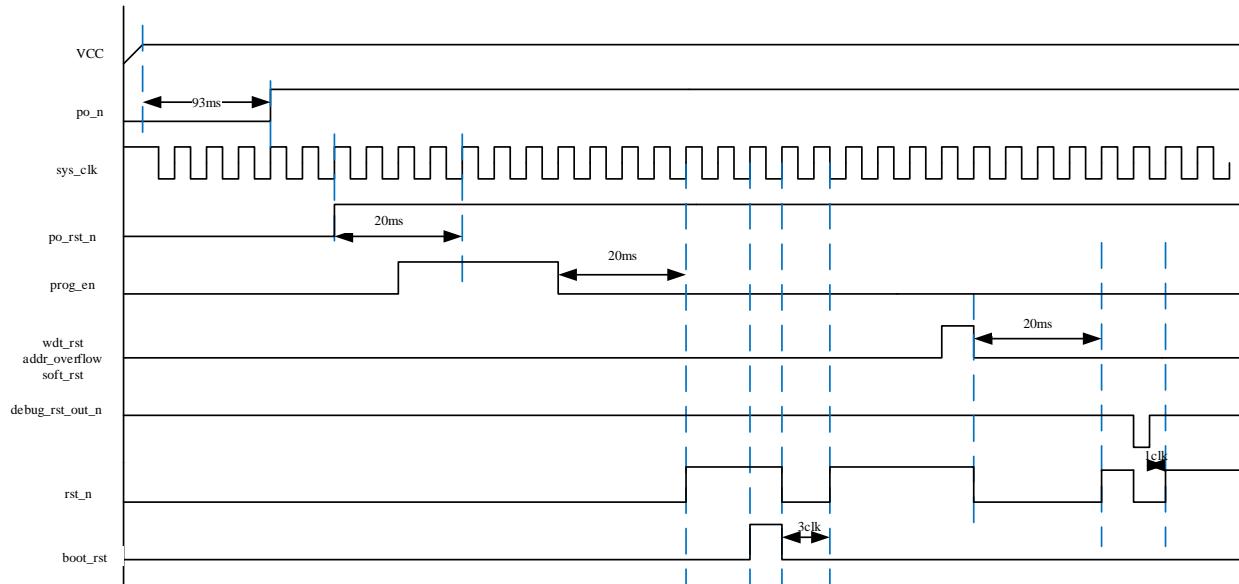

**wdt\_RST:** The watchdog timer overflows and resets. After the watchdog timer overflows, the global reset is 20ms. After 20ms, the system exits the reset mode.

**addr\_overflow:** PC pointer overflow reset. If the PC pointer exceeds the valid address range of flash when the MCU addresses the program memory, the addr\_overflow signal becomes high, and the rising edge of the sys\_clk clock detects the high level of addr\_overflow (requires 1 clock cycle) and resets the global 20ms, the reset signal will clear the addr\_overflow signal to zero. After 20ms, the system exits the reset mode.

**addr\_overflow:** PC pointer overflow reset. If the PC pointer exceeds the valid address range of the flash when the MCU addresses the program memory, the addr\_overflow signal becomes high, and the sys\_clk clock rising edge detects the high level of addr\_overflow (requires 1 clock cycle) and resets the global 20ms, the reset signal will clear the addr\_overflow signal to zero. After 20ms, the system exits the reset mode.

**debug\_rst\_out\_n:** trim configuration reset, output a reset signal for the core trim module, low means reset is effective, chip global reset, but there will not be a 20ms initialization process, only delay 1 system clock reset low level.

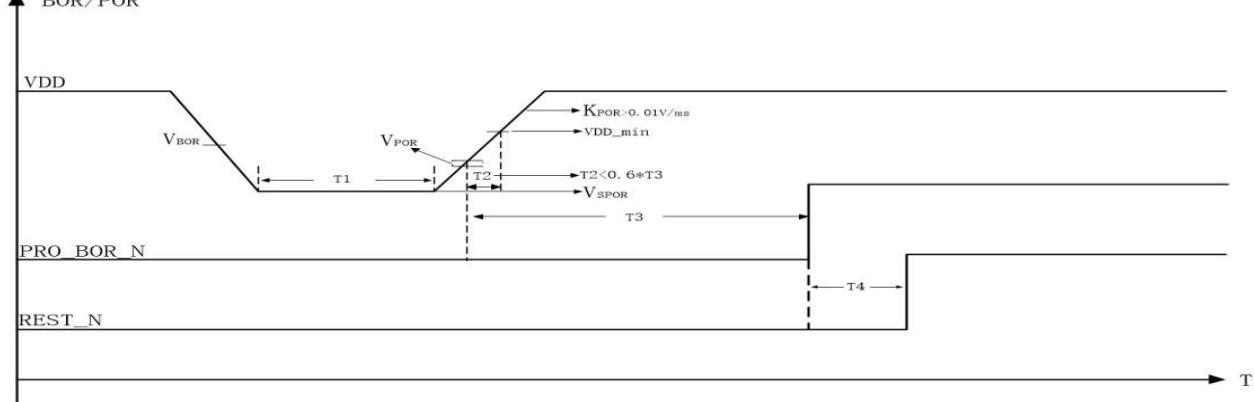

**boot\_rst:** ROM address jump reset, the boot\_rst signal becomes high after the complete ROM space jump instruction is configured, and the sys\_clk clock checks the boot\_rst high level (valid for one clock cycle) to reset the global, but there will be no 20ms read configuration word process , Only delay the reset low level of 3 system clocks.

## Reset sequence description:

1. The chip has a power-on reset, and the analog POR module delays for 93ms, and po\_n is pulled high.
2. The programmer sends instructions to make the chip enter the programming mode (prog\_en is pulled high), and exits the programming mode after completing the programming. After a delay of 20ms, rst\_n is pulled high and the chip enters normal operation.
3. During normal operation, any one of watchdog reset, address overflow reset, and soft reset occurs, rst\_n is pulled low, after a delay of 20ms, rst\_n is pulled high, and the chip enters normal operation.
4. After normal work, you can no longer enter the programming mode.
5. In debug mode, configure debug reset, pull rst\_n low, and after debug\_rst\_out\_n pull high 1 system clock, rst\_n pulls high, the chip enters normal operation.
6. When the chip supports the BOOT upgrade function, a ROM address jump reset occurs, rst\_n is pulled low, and after 3 system clocks, rst\_n is pulled high, and the chip enters normal operation.

Symbol	Parameter	Min	Typ	Max	Unit
VSPOR	Power on reset start voltage	-	-	300	mV
KPRO	Power on reset voltage rate	0.01	-	-	V/ms
VPOR	Power on reset voltage	1.1	1.5	2.2	V
VBOR	Brownout reset voltage ( $\pm 10\%$ ), hysteresis 0.2V	-	VSPOR	-	V
VDD_min	Minimum operating voltage	2.5	-	-	V
T1	VDD keep VSPOR time	0.1	-	-	ms
T2	VPOR from VDD_min time	-	-	0.6*T3	ms
T3	Reset POR_BOR_N duration	55	93	131	ms
T4	Global reset effective time	-	20	-	ms

Power on reset parameter characteristic table

Note: The value of the power-down reset voltage VBOR is selected by register BOR\_SEL[2:0].

When VDD is affected by the load or severely disturbed, if the voltage drops into the voltage

dead zone and the chip is not within the working voltage range, it may cause the system to work abnormally, such as EEPROM-like data loss. The function of power-down reset (BOR) is to monitor when VDD drops to the BOR voltage, the MCU can generate a power-down reset in advance to avoid system errors.

Suggestions to prevent entering the voltage dead zone and reduce the probability of system error:

- When the program is first initialized, open BOR without delay
- Increase the voltage drop slope

### 5.3.2. Reset Register

## 5.4. Working Mode

The BF7613BMXX-XJLX series has 3 working modes, which can be selected according to different situations.

The BF7613BMXX-XJLX provides the SYS\_CLK\_CFG register, whose BIT2 can be configured to control the MCU into WAIT mode. The BF7613BMXX-XJLX provides the PCON register, the Bit0 of which can be configured to control the MCU into low power mode.

### ● Active mode

That is, the normal working mode, the modules keep working normally, and the functions of each module are controlled by the software configuration.

### ● Wait mode

Enter Wait mode by writing 1 to SYS\_CLK\_CFG.2. Core related modules, UART0 ~1 and PWM0 ~2 modules do not work, other modules can work and exit this mode by interrupt.

### ● Low\_power mode

Enter low power mode by writing 1 to PCON.0. RC1M and PLL off, LIRC working, WDT/Timer2 configurable working. CPU and other digital modules are not working.

Working mode conversion diagram

**Ways to exit Wait mode:**

- Enable any one of IIC, External Interrupt0, External Interrupt1, External Interrupt2, External Interrupt3, WDT, Timer2, LED, CSD, ADC, LVDT can wake up the chip, exit the Wait mode, and the CPU executes the interrupt service routine.

**Ways to exit Low\_power mode:**

- Enable IIC, External Interrupt0, External Interrupt1, External Interrupt2, External Interrupt3, WDT, Timer2, any of them can wake up the chip and exit the Low\_power mode. After the interrupt response is generated, the CPU executes the interrupt service routine related to the interrupt vector. And after the RETI return instruction is executed, it returns to the next instruction that causes the CPU to enter the Low\_power mode to continue running the program.

**Note:** PCON = 0x01, BOR off can obtain lower power consumption, but the chip needs to ensure that it is in the normal operating voltage range (2.5V~5.5V), if the chip power supply is unstable, resulting in less than 2.5V, it is strongly recommended that BOR be turned on.

Mode	Conditions for entering this mode	Effect on the clock	
Active/Wait	PCON=0	LIRC	work
		XTAL32K	Depends on software configuration
		RC1M	work
		PLL	work
Low Power	PCON=1	LIRC	work
		XTAL32K	Depends on software configuration
		RC1M	close
		PLL	close

## 5.5. WDT

The WDT timing counting circuit uses the internal low-speed clock LIRC for timing, and the configurable timing time is  $2^n \times 18\text{ms}$  ( $n=0,1,2,3,4,5,6,7$ )---- Here n is the configuration value of the timing configuration register.

Classification of WDT overflow signals due to the particularity of the system applications:

In normal mode, if the WDT overflow occurs, the overflow signal is the WDT overflow reset signal, the WDT overflow reset affects the global reset. At this point, the system implements a global reset action and reloads the configuration information.

In Low\_power mode, if the WDT overflow, the overflow signal is the WDT interrupt signal. Interrupt wake-up chip exits Low\_power mode and executes WDT interrupt service function.

The watchdog module is a timing counting module. Its count clock is the internal low-speed clock LIRC. Its timing clear signal is composed of global reset and configuration clear. This signal is synchronously released by the watchdog timing clock in the reset module; The clearing action is generated every time the CPU configures the watchdog timer configuration register (WDT\_CTRL), and the watchdog restarts timing; at the same time, the watchdog counter has the watchdog count enable control, when the count enable is valid, After the watchdog generates a timing overflow (reset or interrupt), as long as the watchdog counting enable is not turned off, the watchdog counter will restart counting.

INT\_PE\_STAT(85H)WDT/Timer2 interrupt status register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	-	INT_WDT_STAT	INT_TIMER2_STAT
R/W	-	-	-	-	-	-	R/W	R/W
Reset value	-	-	-	-	-	-	0	0

Bit number	Bit symbol	Description
1	INT_WDT_STAT	WDT interrupt status, set 0, write WDT_CTRL can set 0. 1: interrupt effective 0: invalid interrupt

WDT\_CTRL(91H) WDT timing overflow control register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	-	WDT_TIME_SEL	
R/W	-	-	-	-	-	-	R/W	
Reset value	-	-	-	-	-	-	0	0

Bit number	Bit symbol	Description
7~0	WDT_TIME_SEL	WDT overflow timer register. Timing length is as follows: 0x00: 18ms; 0x01: 36ms; 0x02: 72ms; 0x03: 144ms; 0x04: 288ms; 0x05: 576ms; 0x06: 1152ms; 0x07: 2304ms;

The watchdog uses the internal low-speed clock LIRC to complete the timing function and can achieve timing from 18ms to 2.3s. The timing length is controlled by SFR (WDT\_CTRL), as shown in the following table

## WDT\_EN(92H) WDT timing enable register

Bit number	7	6	5	4	3	2	1	0
Symbol	WDT_EN							
R/W	R/W							
Reset value	0							

Turn off WDT when writing 0x55, write other values to enable WDT, the WDT always works after the reset is over. Clearing the WDT is done by writing to the WDT\_CTRL register. Whichever values is written to this register will clear the WDT.

Bit number	Bit symbol	Description
7	IE7	WDT/Timer2 interrupt flag 1: there is a WDT/Timer2 interrupt flag; 0: no WDT/Timer2 interrupt flag

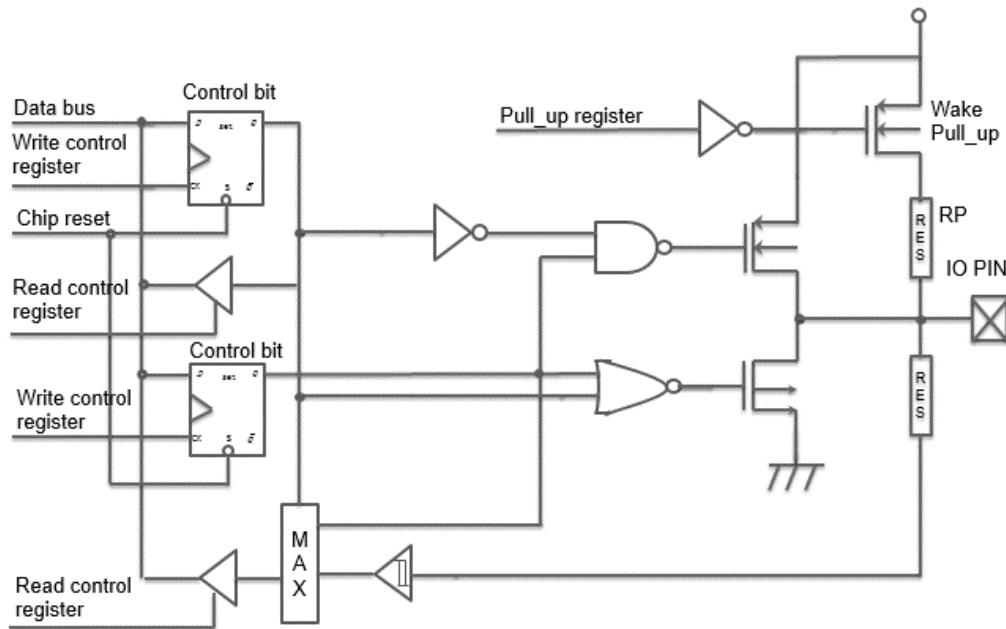

## IPL1 (F6H) Interrupt priority register 1

Bit number	7	6	5	4	3	2	1	0
Symbol	IPL1.7	IPL1.6	IPL1.5	IPL1.4	IPL1.3	IPL1.2	-	-
R/W	R/W	R/W	R/W	R/W	R/W	R/W	-	-
Reset value	0	0	0	0	0	0	-	-

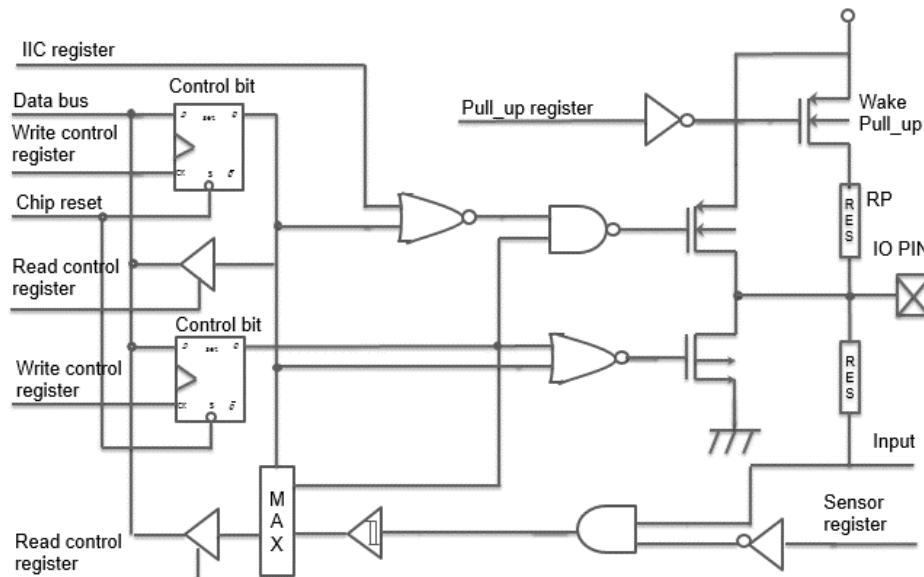

Bit number	Bit symbol	Description
7	IPL1.7	WDT/Timer 2 interrupt priority. 0: low priority; 1: high priority

## 6. GPIO

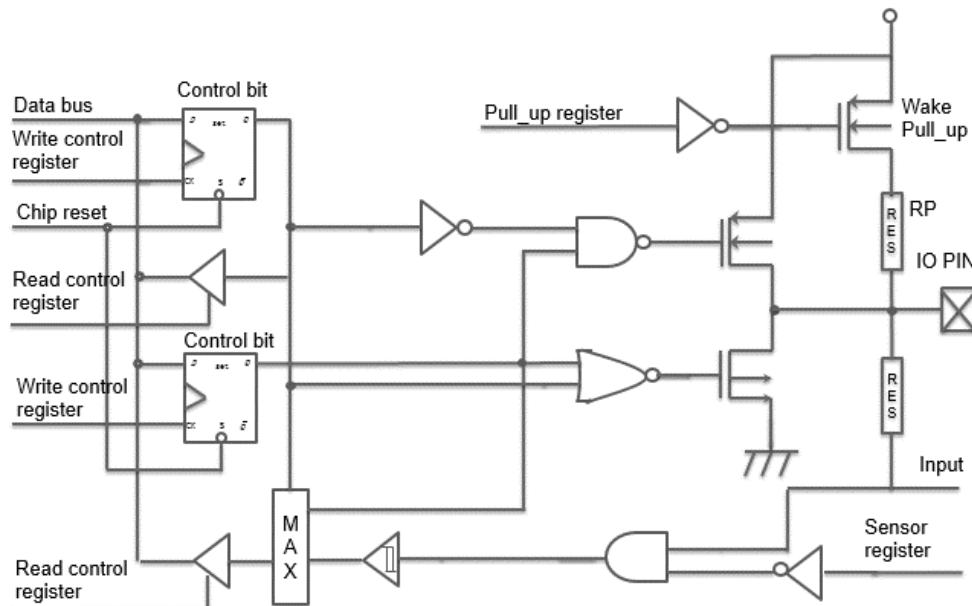

Some pins of the GPIO port are multiplexed with device peripheral functions, and cannot be configured as multiple clock functions at the same time, otherwise it will cause malfunction. IIC communication port, open-drain output, pull-up resister required.

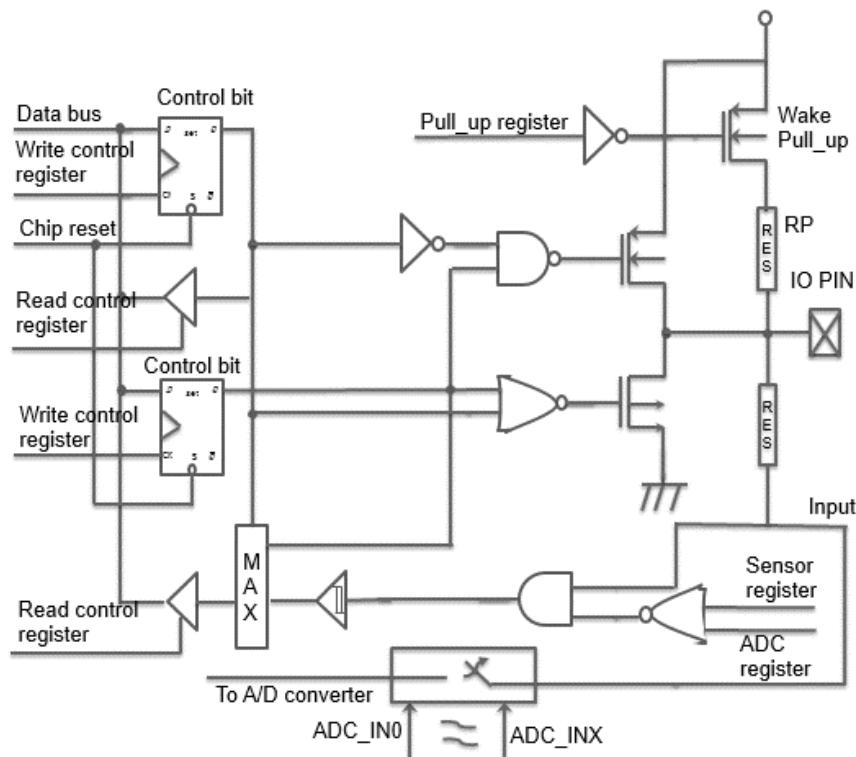

General IO structure

Open-drain output structure

SNS IO structure

**TRISX register (Direction Register):** TRISX set to 1 can be configured as input pin, set to 0 can be configured as output pin.

**DATAX register (Data Register):** DATAX set to 1 the data in DATAX will be configured as high, set to 0 the data in DATAX will be configured as low.

**PU\_PX register (Pull-up resistance enable register):** PU\_PX set to 1 corresponding pin pull-up

resistor enable, clear the corresponding pin does not enable pull-up resistor, and pull-up resistor 4.7K(PB port pull-up resistor 33K).

PD\_PB register (PB pull-down resistor enable register): Set PD\_PB to 1 to enable the corresponding pin pull-down resistor, clear the corresponding pin to disable the pull-down resistor, built-in pull-down resistor 33K.

ODRAIN\_EN register: ODRAIN\_EN set to 1 corresponding pin will enable open drain output, set to 0 corresponding pin output disenabled, automatically turn on open-drain after enabling IIC function. IIC/UART recommends using external pull-up resistors.

Supports 8 GPIO ports for high current drive functions.

Bit number	Bit symbol	Description
7~0	PD_PBn (n=7~0)	PB port pull-down resistor control register 1: The pull-down resistor is enabled; 0: The pull-down resistor is not enabled

### 6.3. GPIO Configuration Process

When setting the port to GPIO, the following three sets of registers need to be set accordingly.

IO configuration flow chart

**Notes:**

The default source current drive capability of the IO port is typically 20mA, the sink current drive capability typically 65mA @5V 0.9VCC. When using IO to drive the LED/digital tube, you need to pay attention to the Ifp current of the LED lamp. It is recommended to add a current limiting resistor to limit the IO drive peak current to the LED/digital tube Ifp current.

List of interrupt information

When the chip generates a reset signal, the program starts from the 0x0000 address. When an interrupt signal occurs, the program will jump to the interrupt vector program address to execute the interrupt service routine.

## 7.2. Interrupt Function

### 7.2.1. Interrupt Response

When an interrupt request, CPU according to the interrupt vectors determine the type of interrupt service routine (ISR) to run. CPU complete execution ISR, unless a higher priority interrupt source applying for a break. After each ISR has RETI (return from interrupt) instruction. After RETI instruction, CPU continues to execute the program before the interrupt did not happen.

ISR can only be a higher priority interrupt request interrupt. That is, the low-priority ISR can be interrupted by a high-priority interrupt request.

The BF7613BMXX-XJLX responses interrupt request until the current instruction finished. If the RETI instruction is being executed or read IPL, IEN register, after an additional instruction then respond the interrupt request.

## 7.2.2. Interrupt Priority

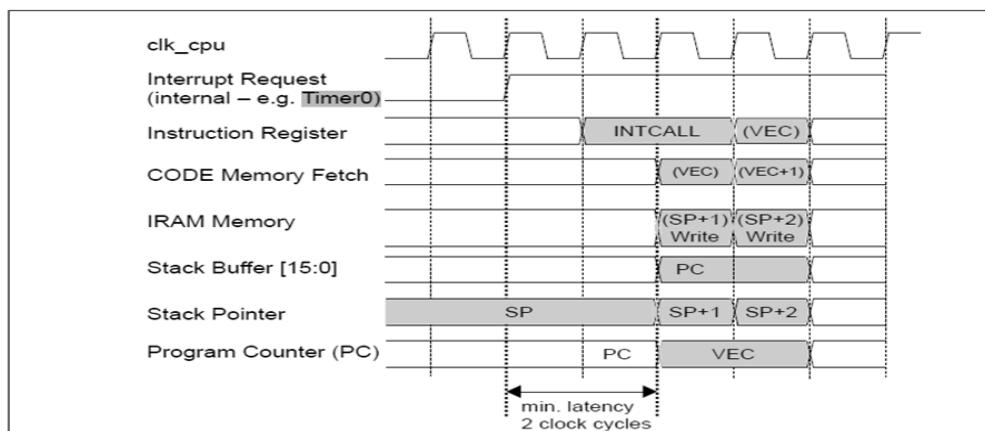

The BF7613BMXX-XJLX has two interrupt priority levels: interrupt level and default priority. Interrupt levels (highest, high, and low) take precedence over the default priority. The priority set to high is the first to respond. When the priority is set to the same level, the response will be queued by default. If allowed, the power-down interrupt is the only highest-level interrupt source. Other interrupt sources can be set to high priority or low priority.

Each interrupt source can be assigned a priority level (high or low), and the default priority. The same level of interrupt sources (such as both high priority) the priority is the default priority decision. Interrupt service routine in progress can only be a high-priority interrupt request interrupt.

## 7.2.3. Interrupt Sampling

Internal modules such as internal timers and serial ports generate interrupt requests through interrupt flag bits in their respective SFRs. At the end of first clock per instruction cycle (C1), at the rising edge of the external interrupt system clock sampling.

To ensure edge-triggered interrupt is detected, the corresponding port must maintain high level for two clocks and maintain low for level two clock.

Interrupt sampling timing diagram

## 7.2.4. Interrupt Wait

Interrupt response time is determined by current state. Fastest response time is five instruction cycles: one cycle to detect the interrupt request, the other 4 used to execute long call (LCALL) to ISR.

When the system is executing a RETI instruction and is followed by a MUL or DIV instruction, the interrupt waits for the longest time (13 instruction cycles). This 13 instruction cycles are as follows: one cycle to detect the interrupt request, three to complete the RETI, five used to execute DIV or MUL instruction, 4 used to execute long call (LCALL) to ISR. In this case, the response time is 13 clock cycles.

Note: INT3 shares an interrupt vector and can only respond to one external interrupt at the same time. When the multi-channel pin external interrupt rising edge or falling edge trigger is enabled, all the enabled external interrupt pins must be released during the detection process to respond to the current trigger signal (when the falling edge is triggered, the release is high. When the rising edge is triggered, the release is low).

## 7.4. External Interrupt Configuration Process

INT0/1/2/3 configuration process chart

## 8. Timer

The BF7613BMXX-XJLX contains three Timers (Timer0/Timer1/Timer2). Each Timer contains a 16-bit register that appears as two bytes when accessed: a low byte (TL0 or TL1) and a high byte (TH0 or TH1). Timer2 register is low byte TIMER2\_SET\_L, high byte TIMER2\_SET\_H.

### Timer features:

- 2 16-bit Timers, 1 32-bit Timer;
- Timer0 connection system clock, partial frequency within the clock sys\_clk/12;
- Timer1 connection system clock, partial frequency within the clock sys\_clk/12;
- Timer2 optional internal RC or external crystal clock, frequency 32768Hz;
- Timer0 support 8bits automatic reload timing/counting, 16bits manual reload timing/counting function;
- Timer1 support 8bits automatic reload timing/counting, 16bits manual reload timing/counting function;
- Timer2 support 32bits automatic reload timing and manual reload timing, support interrupt wake-up function.

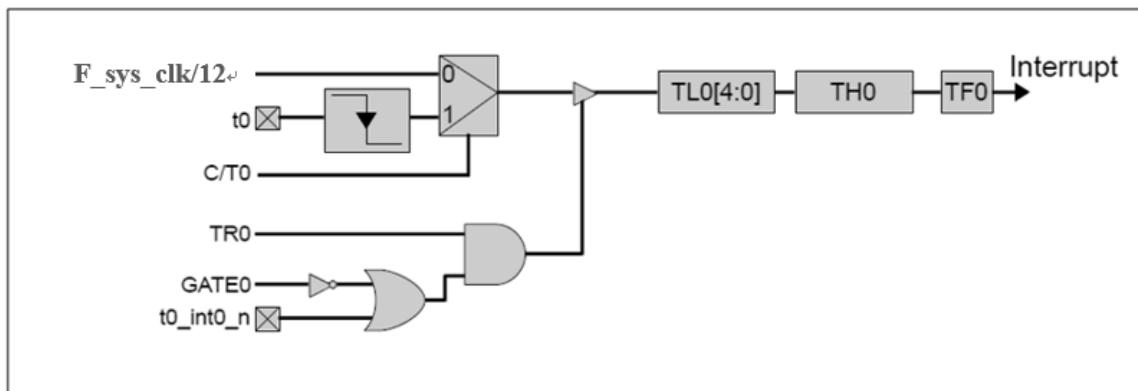

### 8.1. Timer0 and Timer1

The Timer 0/1 has four operating modes, controlled by TMOD SFR and TCON SFR.

Timer0/1 four modes of operation as follows:

- 13 bit timer / counter (mode 0)
- 16 bit timer / counter (mode 1)
- Automatic overload 8-bit counter (mode 2)
- Two 8-bit timer / counter (Mode 3, only for timer / counter 0)

#### Mode 0:13 bit timer / counter

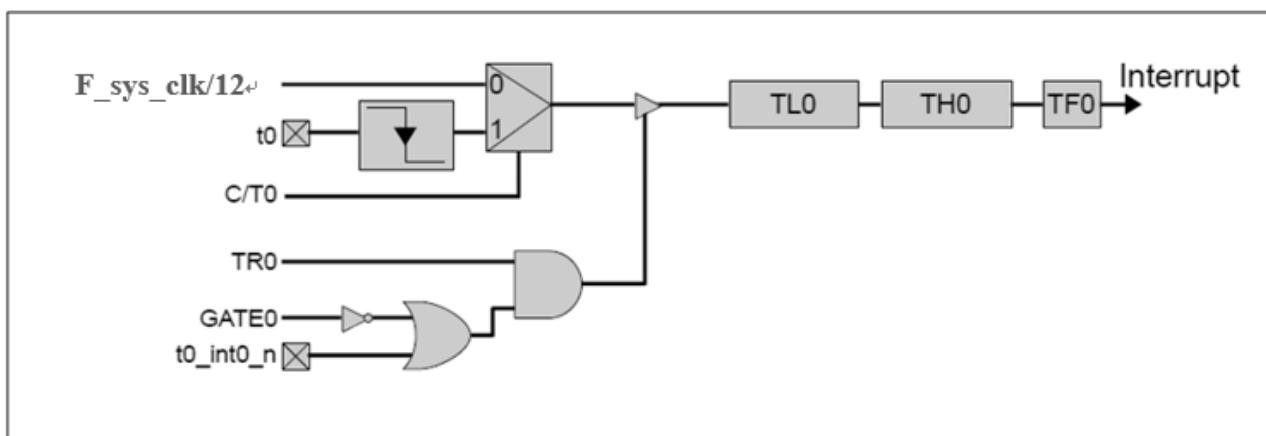

Mode 0 logical structure diagram

In mode 0, timer 0 and timer 1 work the same process, at the picture shows. In mode 0, Timer is 13bit counter, bit0-4 is TL0 (or TL1), other 8 bits is TH0 (or TH1). In TCON register (TR0/TR1) to control timer0/1 start or stop.

The Timer counts the selected clock source(clk/12); When the 13bit counter counts up to all 1, the counter is cleared to 0(all 0) and TF0(or TF1)is set. In mode 0, TL0 (or TL1) high 3bit is not sure. These 3bit should be masked or ignored when reading the count value. t0/t1, C/T0/CT1 all 0, t0\_int0\_n/t1\_int1\_n all 1, count enable is only TR0/1.

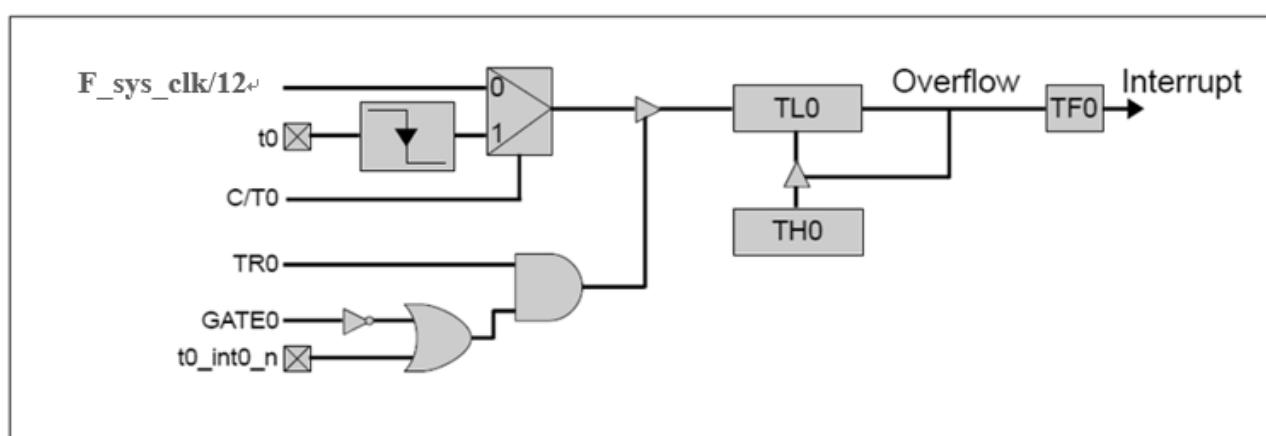

### Mode 1: 16 bit timer / counter

Mode 1 logical structure diagram

In mode 1, timer 0 and timer 1 work the same process. At the picture shows, in mode 1, Timer is 16bit counter, all 8 bits of the LSB register (TL0 or TL1) are used. When the counter count is accumulated to 0xFFFF, the counter is cleared to 0. In addition, mode 1 and mode 2 are the same. t0/t1, C/T0/CT1 all 0, t0\_int0\_n/t1\_int1\_n all 1, count enable is only determined by TR0/1.

### Mode2: reload initial value 8bit counter

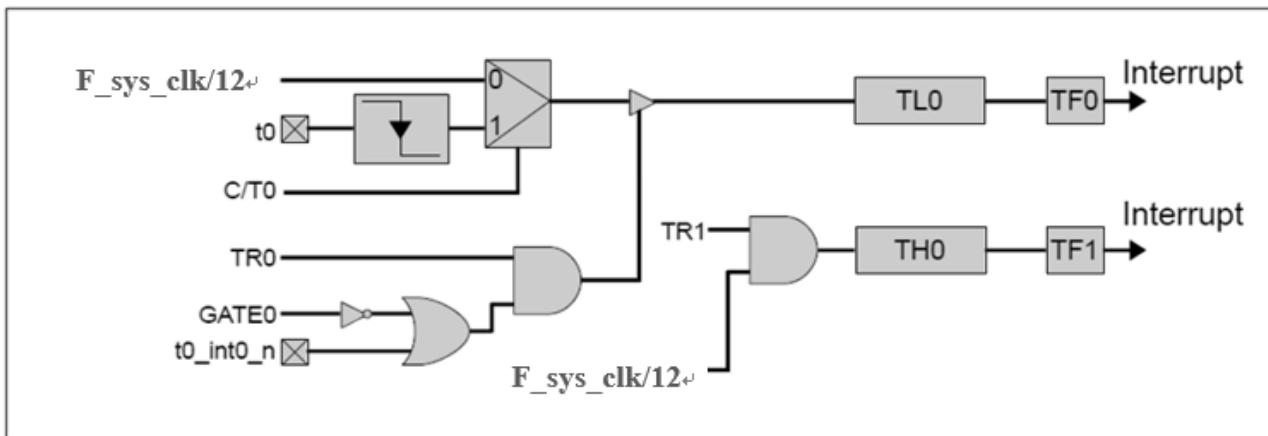

Mode 2 logical structure diagram

The modes of Timer0 and Timer1 are the same. In mode 2, the Timer is an 8bit counter with an automatic reload initial value. This counter is the LSB register (TL0 or TL1). The initial value that needs to be reloaded is saved in the MSB register (TL0 or TL1).

At the picture shows, mode 2 counter control is the same as mode 0 and mode 1. But in mode 2, When the TLn count is accumulated to FFh, the value stored in THn is overloaded to TLn. t0/t1, C/T0/CT1 all 0, t0\_int0\_n/t1\_int1\_n all 1, count enable is only determined by TR0/1.

### Mode3: Two 8bit counter

Mode 3 logical structure diagram

In mode3, timer0 is two 8bit counter, then timer 1 stop count and save the value. Show as below, TL0 is an 8-bit register controlled by the control bit of Timer0. The counter uses GATE as the enable terminal to control the INT\_EXT signal reception.

TH0 is a separate 8-bit counter. TH0 only used to count the clock cycle (12 division). Timer1 control bit and flag bit (TR1 and TF1) used as the TH0's control bit and flag.

When timer0 working in mode3, the use of Timer 1 is limited because Timer 0 uses the Timer 1 control(TR1) and interrupt flags(TF1). Timer 1 can still be used to generate baud rate. The value of TL1 and TH1 is still effective.

When timer0 working in mode 3, though mode control bit of Timer1 to control Timer1. In order to start timer1, need to set Timer 1 to mode 0, 1 or 2. Configure timer1 working in mode3, make timer1 stop. Timer 1 can be used as a Timer (clock is clk/12), However, since TR1 and TF1 are borrowed, overflow interrupts cannot be generated. When timer0 working in mode 3, timer1's GATE is effective. t0/t1, C/T0/CT1 all 0, t0\_int0\_n/t1\_int1\_n all 1, count enable is only determined by TR0/1.

### 8.1.3. Timer0/1 Configure Process

Timer0/1 configure process

## 8.2. Timer2

Timer2 module plays a timing role, the internal structure of the Timer2 module is a 32-bit counter. Timed function by counting the input clock, the counting principle of Timer2 is the accumulation counts to the set value. Timer2's count clock can be selected from the external XTAL clock and the internal RC clock. Timer2 has two working modes: signal time mode and automatic reload mode, regardless of the mode, the timing is completed and an interruption occurs.

TIMER2\_EN configuration Timer2 function enable, TIMER2\_RLD configuration automatic reload mode and manual reload mode. Timing time is determined by registers TIMER2\_SET\_L and TIMER2\_SET\_H. The time clock can choose LIRC and XTAL32768Hz, which is determined by the clock selection register. Timer2 support interrupt wake up in low\_power mode, software clear interrupt flag is required in the interrupt handler.

Timer2 timing duration formula:

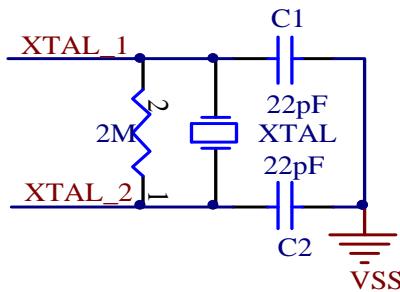

TIMER2\_CNT\_MOD=0:

$$T_{\text{TIMER2}} = T_{\text{TIMER2\_CLK}} * (\{ \text{TIMER2\_SET\_H}, \text{TIMER2\_SET\_L} \} + 1)$$

TIMER2\_CNT\_MOD=1:

$$T_{\text{TIMER2}} = 65536 * T_{\text{TIMER2\_CLK}} * (\{ \text{TIMER2\_SET\_H}, \text{TIMER2\_SET\_L} \} + 1)$$

Note:  $T_{\text{TIMER2\_CLK}} = 1/32768$  (s)

External crystal oscillator circuit reference

### Notes:

1. Arbitrary configuration TIMER2\_SET\_H, TIMER2\_SET\_L, TIMER2\_CFG will clear counter;
2. External crystal oscillator circuit is for reference only, actual reference crystal specifications.

### 8.2.3. Timer2 Configure Process

Timer2 configure process table

In the configuration process:

1. First configure the timing set value register TIMER2\_SET\_H/TIMER2\_SET\_L and step configuration TIMER2\_CNT\_MOD;
2. Then automatically reload the enable register TIMER2\_RLD according to the configuration, set to 1 if automatic loop count is required, otherwise configure 0;
3. Final configuration timing enable register TIMER2\_EN, enable timing configuration TIMER2\_EN=1;
4. Stop timing: TIMER2\_EN=0.

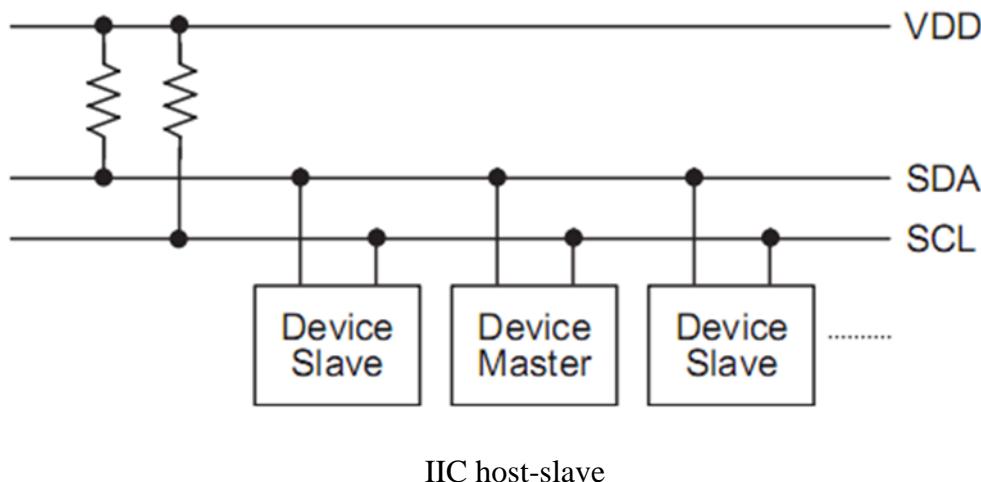

**Notes:**

1. **TIMER2\_EN=0x1 to be placed at the end of all configurations;**
2. **During the TIMER2 timing, it is forbidden to change the configuration of Timer2. To modify, you need to stop timing first;**
3. **For precise timing, in the auto-reload mode, it is not allowed to configure three registers of TIMER2 in interrupt processing.**

## 9. IIC

The BF7613BMXX-XJLX supports standard and fast IIC communication, and has the following characteristics:

- Two serial interfaces: serial data line SDA and serial clock line SCL;
- Meet philips's standard communication protocol;
- Transmission rate: 100Kbps, 400Kbps;
- Support for 7-bit address addressing;
- Has the function of extending the clock low level;
- Wake-up core can be interrupted by IIC in low\_power mode;
- Detect write conflicts and cache BUF overflow exceptions;
- Support digital filter function and analog filter function of IIC port.

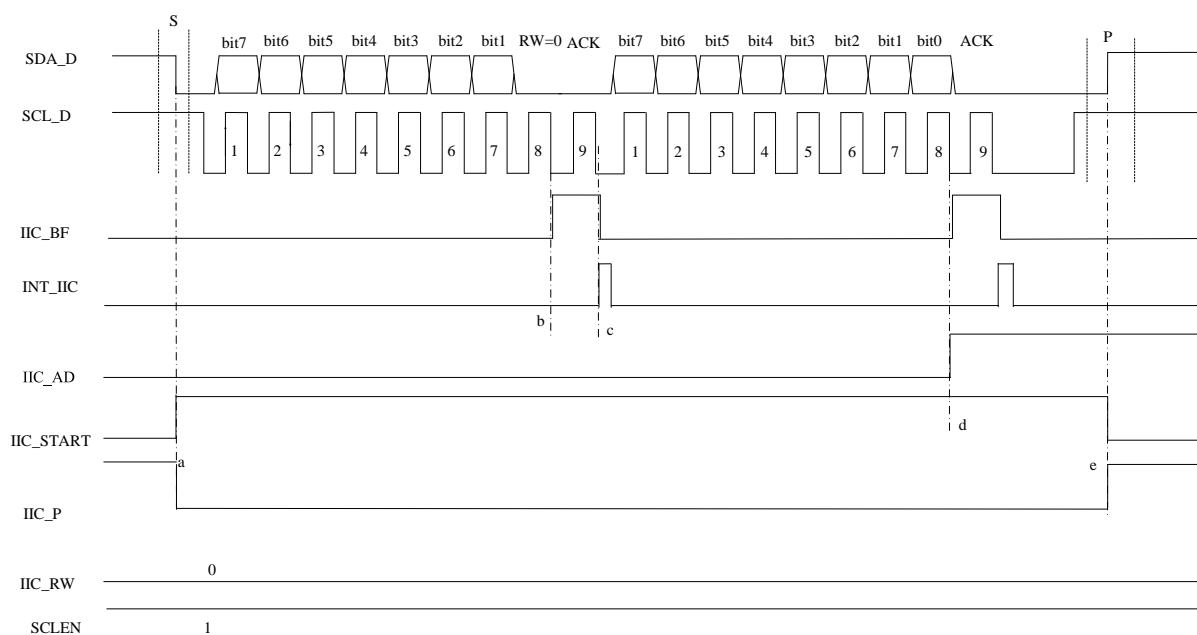

IIC host-slave

The host and slave from the SCL (serial clock) line, SDA (serial data) wire connection, in the communication mode, the PA0/PA1/PD6 is open drain, SCL, SDA must be connected to the pull resistor(suggest 4.7K~10K). When the TS device has touch related actions, such as touch, slide, figure away, etc. The host can read the state of the slave through IIC communication.

## 9.1. Communication Timing

The BF7613BMXX-XJLX uses hardware slave. When the host reads/writes data, after the slave receives the address, if the address matches, an interrupt is generated and a valid response signal is sent. And an interrupt is generated after the host computer writes the eighth clock of the data, and the host will not generate an interrupt signal when sending the stop signal. IIC timing diagram as follows:

IIC host write timing diagram

IIC write not pull down clock line diagram

As shown in the above figure, the schematic diagram of the clock line is not pulled down during the host write operation. From this, you can see the changes of the IIC bus and some internal signal changes.

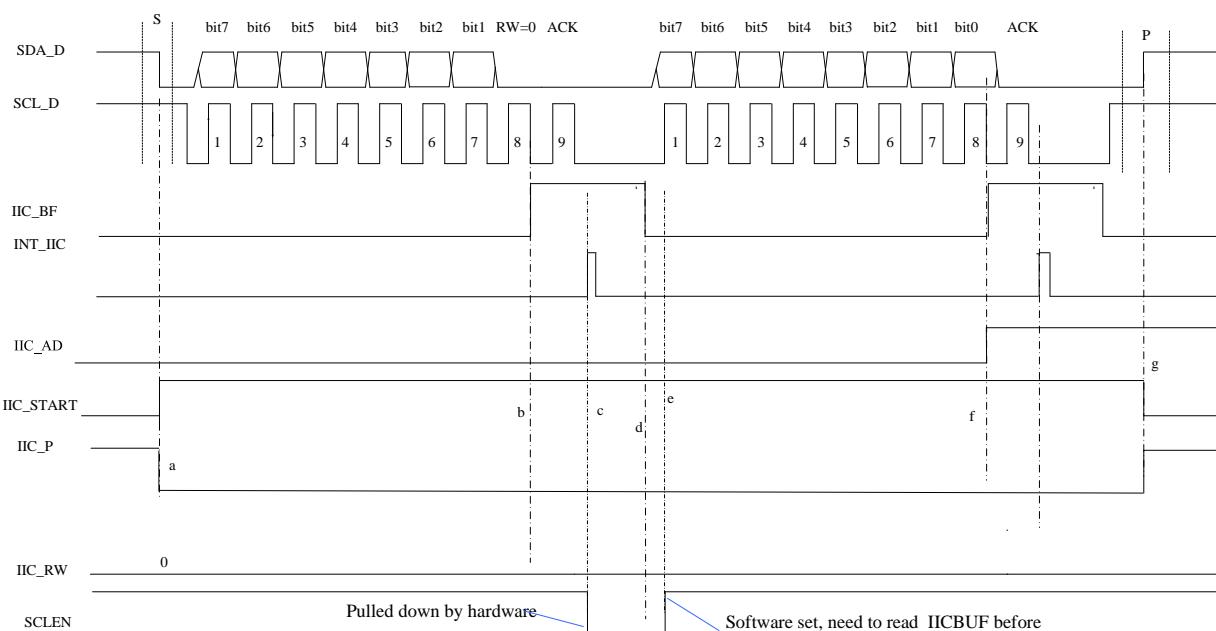

First the host sends a start signal IIC\_START, and the slave sets the IIC\_START status bit after detecting the IIC\_START signal, as shown by the dotted line a in the figure.

Then the host sends the address bytes and write flag bit, and the slave automatically compares with its own address after receiving the address byte. Set IIC\_BF after the falling edge of the eighth clock if the address matches, as shown by the dotted line b in the figure. An interrupt signal INT\_IIC is generated after the falling edge of the ninth clock, as shown by the dotted line c. The MCU executes interrupt subroutine device needs to read IICBUF. Even if this data is not useful, it needs to be operated. Reading the IICBUF operation will indirectly clear the START\_BF. The host continues to send messages. The IIC\_BF is also set after the falling edge of the 8th clock of the 2nd byte, and the IIC\_AD flag is also set. The currently received byte of the flag is data, and the stop signal has no effect on the IIC\_STOP flag. That is, the stop signal IIC\_STOP is detected, as shown by the dotted line d. And the IIC\_AD flag will not be cleared. The interrupt is generated after the falling edge of the ninth clock, and the interrupt subroutine requires the same operation. If the host

wants to send multiple bytes, it can continue to send. The figure above only shows the case where the host sends a data.

Finally, the host sends a stop signal IIC\_STOP after sending all the data, indicating the end of the communication, releasing the IIC bus, and the bus enters the idle state.

### IIC host write pull low timing diagram

IIC write low clock line diagram

As shown in the above figure, it is a schematic diagram of pulling down the clock line during the host write operation, from which you can see the changes of the IIC bus and some internal signal changes.

First the host sends a start signal IIC\_START, and the slave sets the IIC\_START status bit after detecting the IIC\_START signal, as shown by the dotted line a.

Then the host sends the address bytes and write flag bit, and the slave automatically compares with its own address after receiving the address byte. Set IIC\_BF after the falling edge of the eighth clock if the address matches, as shown by the dotted line b.

An interrupt signal INT\_IIC is generated after the falling edge of the ninth clock, as shown by the dotted line c. SCLEN will be cleared by hardware. This process is used to process or read data from the slave. Even if this data is not useful, reading IICBUF will cause IIC\_BUF to be cleared indirectly, as shown by the dotted line d. Software sets SCLEN to release the clock line. As shown by the dotted line e.

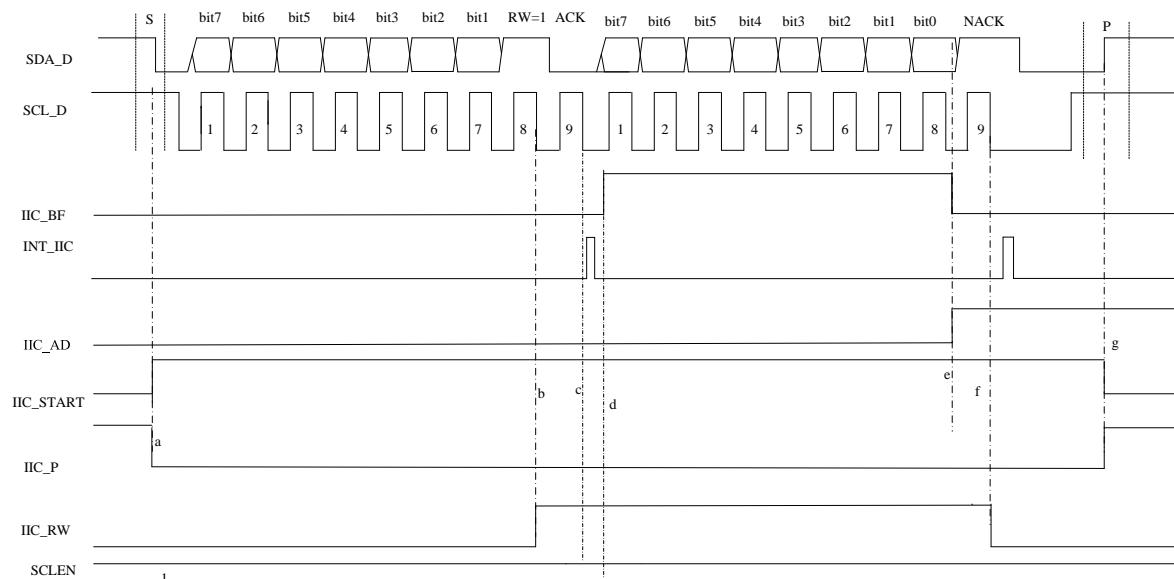

After the master detects that the slave releases the SCL, it continues to send the synchronous clock. The IIC\_BF is also set after the falling edge of the 8th clock of the 2nd byte, and the IIC\_AD flag is also set. And the IIC\_AD flag is also set. The currently received byte of the flag is data, as shown by the dotted line f, and the stop signal has no effect on the IIC\_STOP flag. That is, the stop signal IIC\_STOP is detected, and the IIC\_AD flag will not be cleared; The interrupt is generated

after the falling edge of the ninth clock, and the interrupt subroutine requires the same operation. If the host wants to send multiple bytes, it can continue to send. The figure above only shows the case where the host sends a data.

Finally, the host sends a stop signal IIC\_STOP after sending all the data, indicating the end of the communication, releasing the IIC bus, and the bus enters the idle state.

### IIC host read timing diagram

IIC host does not pull low clock line diagram

As shown in the above figure, the schematic diagram of the clock line is not pulled when the host reads.

First the host sends a start signal IIC\_START, marking the beginning of communication. As shown by the dotted line a. The internal circuit detects the IIC\_START signal timing and sets the status flag IIC\_START.

Then the host sends the address bytes and write flag bit, IIC\_RW = 1, indicates that the host reads the slave. The slave automatically compares with its own address after receiving the address byte. Status bit IIC\_RW set. As shown by the dotted line b. Set IIC\_RW after the falling edge of the ninth clock if the address matches.

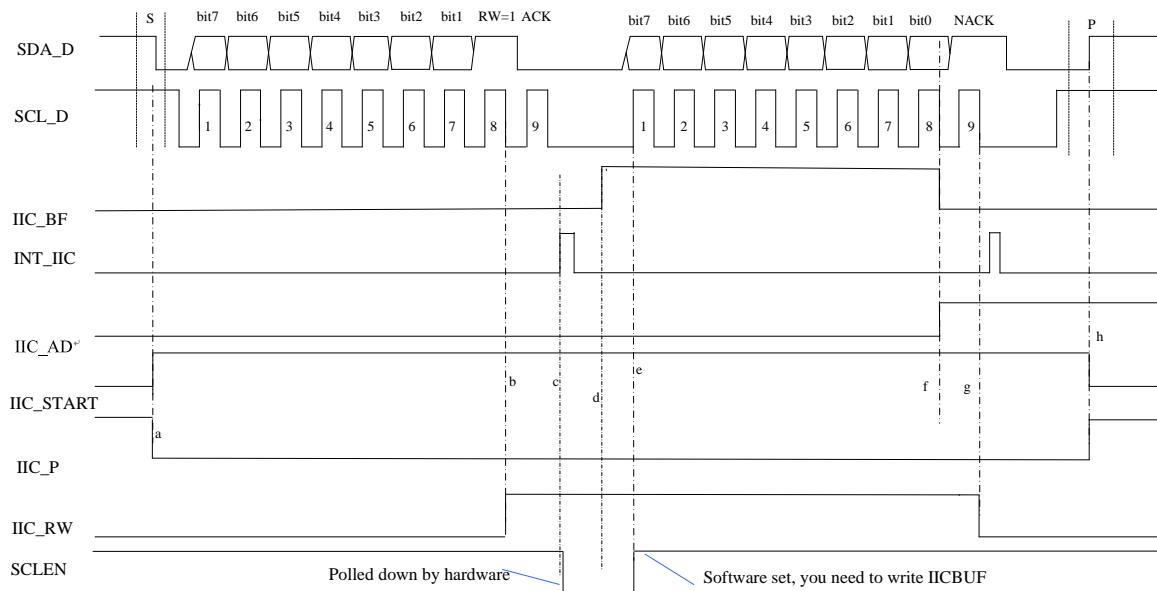

An interrupt signal INT\_IIC is generated after the falling edge of the ninth clock. As shown by the dotted line c. Ballast the data in IICBUFFER to IICBUF, IIC is set to clear, as shown by the dotted line d, and the highest bit is sent to the bus. After the eighth clock, one byte of data is sent, IIC\_BF is set to clear; At the same time, the address data flag will also be set, indicating the currently transmitted byte data.

As shown by the dotted line e. An interrupt signal INT\_IIC is generated after the falling edge of the ninth clock. If the host needs to read the slave, the host replies with a valid acknowledge bit ACK and continues to communicate. If the data require by the host has been read, the host replies with an invalid response NACK, and then sends a stop signal IIC\_STOP to stop the communication.

This should be noted in the application. When the NACK is detected, the read/write flag IIC\_RW is cleared by hardware. As shown by the dotted line f. If the host sends a NACK, the slave SCLEN will not be automatically pulled low.

Finally, the host sends a stop signal IIC\_STOP after reading all the data, indicating the end of the communication. When the IIC\_STOP signal is detected the status bit IIC\_STOP is set and IIC\_START is cleared. Release IIC bus. As shown by the dotted line g. The bus enters the idle state.

### IIC host read pull low timing diagram

### IIC host read pull low clock line diagram

As shown in the above figure, the schematic diagram of the clock line is not pulled when the host reads.

First the host sends a start signal IIC\_START, marking the beginning of communication. As shown by the dotted line a. The internal circuit detects the IIC\_START signal timing and sets the status flag IIC\_START.

Then the host sends the address byte after the IIC\_START signal. IIC\_RW = 1, indicates that the host reads the slave. Status bit IIC\_RW set. As shown by the dotted line b. Will not be set if the addresses do not match.

An interrupt signal INT\_IIC is generated after the falling edge of the ninth clock. As shown by the dotted line c. SCLEN will also be automatically pulled low by the hardware after the falling edge of the ninth clock. This period is used to process or prepare data from the slave, then write the prepared data to IICBUF, set SCLEN in software, and release the clock line. As shown by the dotted line d. In writing the data to the IIC, the IIC will be set, indicating that the IIC is full at this time. As shown by the dotted line e.

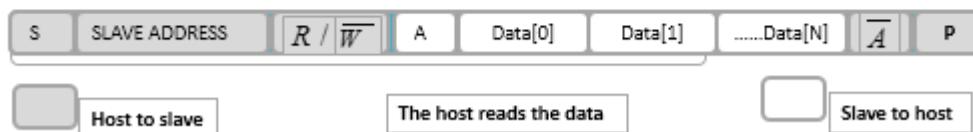

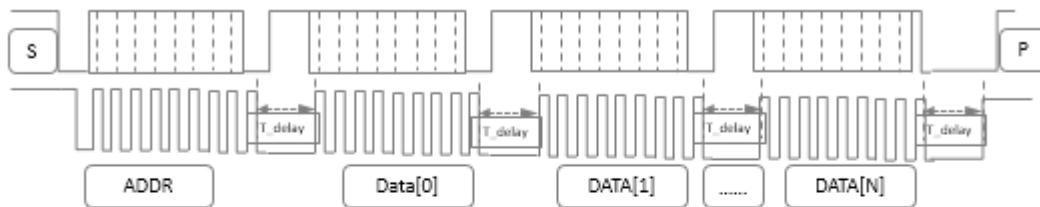

After the master detects that the slave releases the SCL, it continues to send the synchronous clock and read the slave data. After the falling edge of the 8th clock, one byte of data has been sent and IIC\_BF cleared; At the same time, the address data flag will also be set, indicating the currently

transmitted byte data. As shown by the dotted line f.

An interrupt signal INT\_IIC is generated after the falling edge of the ninth clock. If the host needs to continue to read the slave, the host replies with a valid acknowledge bit ACK and continues to communicate; If the data require by the host has been read, the host replies with an invalid response NACK, and then sends a stop signal IIC\_STOP to stop the communication. When the NACK is detected, the read/write flag IIC\_RW is cleared by hardware. As shown by the dotted line g.

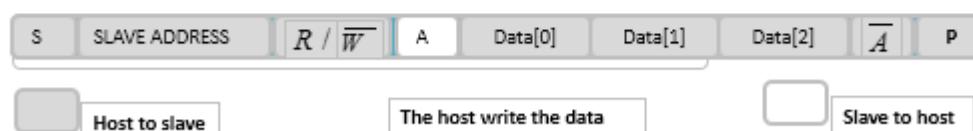

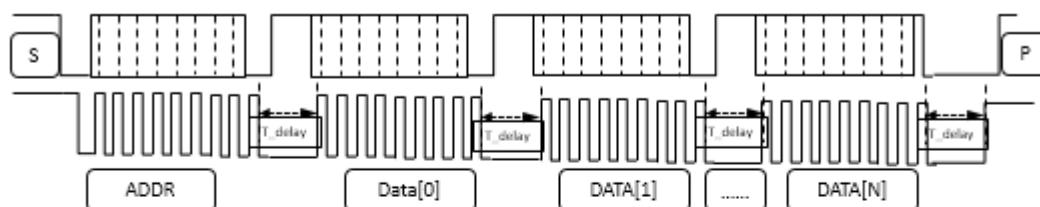

Finally, the host sends a stop signal IIC\_STOP after reading all the data, indicating the end of the communication. When the IIC\_STOP signal is detected the status bit IIC\_STOP is set and IIC\_START is cleared. Release IIC bus. As shown by the dotted line h. The bus enters the idle state.

### IIC host read data diagram

PS: T\_delay: Reserve slave interrupt time, generally 60us~300us, if the slave IIC interrupts the service processing time at100us, suggest T\_delay>200us.

### IIC host write data diagram

PS: T\_delay: Reserve slave interrupt time, generally 60us~300us, if the slave IIC interrupts the service processing time at100us, suggest T\_delay>200us .

At the eighth clock slave send ack, IIC interrupt occurs at the ninth clock fulling edge. It is recommended that the host delay 60us~300us when the ninth clock fulling edge is sent. Reserve the slave IIC interrupt service data preparation time, and then send the clock signal.

**Note: When IIC communication $\geq$ 100K, it is recommended that the system clock is 6MHz.**

Bit number	Bit symbol	Description
7	IIC_START	Start signal flag 1: start bit detected; 0: no start bit detected
6	IIC_STOP	Stop signal flag 1: stop status detected; 0: no stop status detected
5	IIC_RW	Read and write flag. Record the read/write information obtained from the address byte after the last address match. 1: read; 0: write.
4	IIC_AD	Address data flag 1: The most recently received or sent byte is data; 0: The most recently received or sent byte is address
3	IIC_BF	IICBUF full flag. Received in IIC bus mode: 1: received successfully, buffer is full; 0: received successfully, buffer is empty. Send in IIC bus mode 1: data transmission is in progress (does not include the acknowledge bit and the stop bit), buffer is full; 0: data transmission has been completed (does not include the acknowledge bit and the stop bit), buffer is empty.
2	IIC_ACK	Answer flag 1: invalid response signal; 0: effective response signal.

1	IIC_WCOL	Write conflict flag. 1: when the IIC is transmitting the current data, the new data is attempted to be written to the transmit buffer; new data cannot be written to the buffer. 0: no write conflict
0	IIC_RECV	Receive overflow flag bit 1: When the previous data received by the IIC has not been taken, new data is received, the new data cannot be received by the buffer. 0: no receive overflow.

**IIC\_START:** Start signal status bit, IIC\_START is set when the start signal is detected, indicating that the bus is busy.

**IIC\_STOP:** Stop signal status bit, IIC\_STOP is set when the start signal is detected, indicating that the bus is idle. When the start signal is detected, the hardware is cleared, indicating that communication begins.

**IIC\_AD:** Address data flag. It indicates whether the byte currently received or sent is an address or data. IIC\_AD = 0, flag is currently received or sent byte is the address; IIC\_AD = 1 flag is currently received or sent byte is the data; Start signal, stop signal, non-response signal have no effect on this status bit. This status bit change occurs on the falling edge of the eighth clock.

**IIC\_RW:** Read and write flag. The flag bit is recorded the read and write information bits obtained from the address is matched. IIC\_RW = 1 means the host reads the slave. RW = 0 means the host writes the slave. Start signal, stop signal, non-answer signal (NACK) is cleared IIC\_RW. This status bit change occurs on the falling edge of the ninth clock.

**IIC\_BF:** BUFFER full flag. It indicates that the transceiver buffer is currently full or empty. IIC\_BF=0 indicates that the buffer does not receive data and the buffer is empty; IIC\_BF=1 indicates that the buffer receive data and the buffer is full. This status bit can only be set and cleared indirectly, not directly.

Address matching and IIC\_RW=0, IIC\_BF will be set after the falling edge of the eighth clock, indicating that the IICBUF has received the data. The IICBUF should be read during the execution of the interrupt routine, and the read IICBUF will indirectly clear the BF flag. If the host does not read IICBUF and the host continues to send data, a receive overflow will occur. Although the slave still receives the host to send data and is ballasted to the IICBUF.

IIC\_RW=1 indicates the operation of the master to read the slave, the slave operation needs to write data to the IICBUF, and the slave writes IICBUF operation to set the IICBUF. The software then sets SCLEN to release the clock line; The host sends the synchronous clock. After the 8th clock is passed, the IICBUF is cleared by hardware after the data in the IICBUF is sent out.

**IIC\_ACK:** Answer flag. Regardless of whether the host is a read or write operation, the slave samples the data line from the rising edge of the ninth clock and records the response information. The acknowledge bits are divided into a valid acknowledgment ACK and a non-valid acknowledgement bit NACK. That is to say, the rising edge of the ninth clock samples the data to 0,

indicating that the ACK is valid, and the IIC\_ACK is cleared. If data 1 is sampled, NACK is set, indicating non-response. After the non-acknowledgment signal, the host will send a stop signal to announce the end of the communication. The start signal will clear this status bit.

**IIC\_WCOL:** Write conflict flag. IICBUF only when IIC\_RW=1, RD\_SCL\_EN=1 and SCLEN=0 can be written by the CPU. Any other attempt to write to IICBUF is forbidden. If the above conditions are not met, the write IICBUF operation occurs. Then the data will not be written to IICBUF, and the conflict flag IIC\_WCOL will be set. This flag needs to be cleared by software.

**IIC\_RECV:** Receive overflow flag. In the case of IICBUF full, that is, in the case of data in the IICBUF. If IIC received new data, it will receive overflow and IIC\_RECV will set. At the same time, the data in the IICBUF will not be updated, and the newly received data will be lost. This status bit also requires software to clear, otherwise it will affect the subsequent communication. This kind of situation will only appear in IICRW=0. BF=1, and the CPU will appear when it does not read IICBUF.

### 9.2.3. IICCON Register

The IICCON register is used to control the communication operation.

IICCON (E5H) IIC configuration register

Bit number	7	6	5	4
Symbol	–	–	IIC_RST	RD_SCL_EN
R/W	–	–	R/W	R/W
Reset value	–	–	0	1
Bit number	3	2	1	0
Symbol	WR_SCL_EN	SCLEN	SR	IIC_EN
R/W	R/W	R/W	R/W	R/W
Reset value	0	0	0	0

Bit number	Bit symbol	Description
7~6	--	Reserved
5	IIC_RST	IIC module reset signal 1: IIC module reset operation 0: IIC module works properly
4	RD_SCL_EN	Host read pull low clock line control bit. 1: enable the host to read and pull the low clock line function; 0: disable the host to read and pull the low clock line function.
3	WR_SCL_EN	Host write pull low clock line control bit. 1: enable the host to write and pull the low clock line function; 0: disable the host to write and pull the low clock line function.
2	SCLEN	IIC clock enable bit 1: clock work properly

		0: pull down the clock line.
1	SR	IIC conversion rate control bit 1: Conversion rate control is turned off to adapt to the standard speed mode (100K); 0: Conversion rate control is enabled to adapt to fast speed mode (400K)
0	IIC_EN	IIC work enable bit 1: IIC normal work; 0: IIC not work

The role is describle in detail below:

**IICEN** is module enable signal, when IICEN=1, the circuit works.

**SR** is the conversion rate control bit, SR=1 conversion ratecontrol off, port adapted to 100Kbps communication.

**SCLEN** is clock enable control bit, although the slave cannot generate the communication clock, the slave can extend the low time of the clock according to the protocol. SCLEN=0, clock line is locked at low level; SCLEN=1, release clock line. The premise of extending the low level of the clock is IICEN=1, otherwise the internal circuit will not have any effect on the IIC bus. SCLEN is often used to extend low time and make the host enter the wait state, so that the slave has enough time to process the data.

**WR\_SCL\_EN** is write low line control bit. When it is 1 to enable the interrupt to pull down the clock line, when it is 0, it does not enable the interrupt to pull down the clock line.

IIC\_RW=0, according to the communication rate of the host and the time of processing the interrupt, it is determined whether to lower the clock line, that is, configure the WR\_SCL\_EN bit.

When the CPU can process the interrupt and exit the interrupt within 8 IIC clocks.

WR\_SCL\_EN=0 disable pull down the clock clock line function. At this time, the hardware will not automatically pull down the clock line when the interrupt arrives. When the CPU cannot process the interrupt and exit in the 8 IIC clocks, WR\_SCL\_EN=1 enables the clock line to be pulled down. At this point, the hardware automatically pulls down the clock line when the interrupt arrives, forcing the host to enter the wait state. When the data written to the IIC is read by the CPU, the software sets SCLEN.

**RD\_SCL\_EN** is read low line control bit. When it is 1 to enable the interrupt to pull down the clock line, when it is 0, it does not enable the interrupt to pull down the clock line.

RD\_SCL\_EN=1, when the slave receives the address byte or sends one byte and the host sends, SCLEN will be automatically pulled low by hardware, forcing the host to the enter the wait state. The release the IIC clock from the slave, the following two operations arerequired: first write the data to be sent to the IIC, set the software in IICBUF in SCLEN. The purpose of this design is to ensure that the data to be sent has been written in the IICBUF before the SCL is pulled high.

RD\_SCL\_EN=0, when the slave receives the address byte or sends one byte and the host sends an ACK, the slave immediately polls the data prepared in the IICBUFFER register to the transmit buffer register and then to the data line. Therefore, in order to ensure that data transmitted each time

is correct, IICBUFFER prepares the next data to be sent in the interrupt service routine. The data received by the host is the last interrupted data, and the first time the data is received is ready for initialization.

**Note:** When you need to pull down the clock line, that is, WR\_SCL\_EN/RD\_SCL\_EN=1. Software should turn off the clock line until the last Byte data is sent and received. That is, WR\_SCL\_EN/RD\_SCL\_EN=0, the software should turn on the write low pull clock line before sending and receiving the last Byte data. This kind of operation can be self-regulated according to whether the host is software or hardware.

**IIC\_RST** is IIC module control enable bit, enable the IIC module reset function for 1 and disable the IIC module reset function when 0. Pay attention to configuration 1 reset IIC module all DFF triggers. The reset terminal of IIC\_RST is global reset, and the other reset terminal are iic\_rst\_n. All iic\_rst writes 0 first, then operate other register configurations.

#### 9.2.4. IICBUF Register

The IICBUF register is used to control the communication operation.

IICBUF (E4H) IIC transmit and receive data register

Bit number	7	6	5	4	3	2	1	0
Symbol	IICBUF							
R/W	R/W							
Reset value	0							

Bit number	Bit symbol	Description
7~0	IICBUF	IIC transmit and receive data buffer

The specific application process is as follows:

In the send state, after the data is ballasted into the IICBUF, under the synchronous clock of the host. The data is sequentially shifted and sent out, the high position is in front. After 8 clocks, one byte is sent.

In the receive state, after the host's 8 clocks have passed, the data is written to the BUF. After the 9th clock, an interrupt is generated, telling the CPU to read the data in the IICBUF.

Writing data to IICBUF is conditional, when RD\_SCL\_EN=1, only IIC\_RW=1, and SCLEN=0 can write data into IICBUF; Otherwise, the operation of writing IICBUF is prohibited. That is to say, if the condition is not satisfied, the operation of writing IICBUF cannot be successful, and the data cannot be written. IICBUF data will not change, but will also cause write conflicts.

For example: IICBUF already has been 55h. In case the condition of writing IICBUF is not satisfied, we want to write data 00h into IICBUF. The result is that the data in IICBUF is still 55h, and the write conflict flag IIC\_WCOL is set to tell the user that the operation is abnormal.

When RD\_SCL\_EN=0, the data to be the slave is the value of the ballast IICBUFFER register when the interrupt signal is generated.

### 9.2.5. IICBUFFER Register

IICBUFFER (E9H) IIC transmit and receive data buffer register

Bit number	7	6	5	4	3	2	1	0
Symbol	IICBUFFER							
R/W	R/W							
Reset value	0							

The specific application process is as follows:

When RD\_SCL\_EN=0, and the host reads the data, the data in the IICBUFFER is sent to the slave transmit buffer register after the two clks after the interrupt is generated, and the data is sent as slave. Therefore, the data in the IICBUFFER should be prepared before the interrupt is generated. Generally, it is ready in the service routine. Device address generation interrupts send data to prepare for initialization.

### 9.2.6. Interrupt Register

## 10. UART

There are 2 UART modules in the BF7613BMXX-XJLX series. UART0 supports 5 IO port mapping, and UART1 supports 4 channels. Only one set of mapping can be mapped at the same time. UART module interface characteristics:

- Support full-duplex, half-duplex serial
- Independent dual buffer receiver and single buffer transmitter
- Programmed baud rate (10bit analog-to digital divider)
- Interrupt-driven or polling operation:
  - send completed
  - receiving full
  - receive overflow, parity error, frame error
- Supports hardware parity production and check
- Programmable 8bit or 9bit character length
- STOP bit 1 or 2 can be selected
- Supports multiprocessor mode
- Support TXD/RXD pin position swap
- Support TXD/RXD independent enable

## 10.1. UART Function Description

### 10.1.1. Baud Rate Generation

Baud rate generation modules: Baud\_Mod= {UART0/1\_BDH[1:0], UART0/1\_BDL}.

Baud rate calculation formula: Baud\_Mod=0, does not generate baud rate clock. When Baud\_Mod=1~1023, UART0 baud rate = BUSCLK/(16x Baud\_Mod).

The BUSCLK uses the divided clock of the system clock source, fixed to 24M. Each time the baud rate register is configured, the internal counter is cleared and the baud rate signal is regenerated. Communication requires the transmitter and receiver to use the same baud rate. Baud rate deviation range allowed by communication:  $8/(11*16)=4.5\%$ .

### 10.1.2. Transmitter Function

Send data flow: Trammed by writing UART0/1\_BUF data, sending stop bit after sending stop bit. Software clear interrupt flag and waits for the next write. The transmitter output pin (TXD) idle state defaults to a logic high state. The entire transmission process must be performed when the module is enabled.

By writing data to the data register (UART0/1\_BUF), save the data directly to the send data buffer and start the send process. The data buffer is locked during the subsequent complete transmission. The configuration write data register UART0/1\_BUF and T8 is invalid. After the stop bit is sent, writing to UART0/1\_BUF again will restart the new transmission.

The serial component of the serial transmitter has a length of 10/11/12 (depending on the setting in the data\_mode control bit) transmit shift register. If data\_mode=0, select normal 8bit data mode. In the 8bit data mode, there is 1 start bit in the shift register, 8 data bits and 1/2 stop bits. Send and receive are small endian mode (LSB first).

### 10.1.3. Receiver Function

The receiver is enabled by setting the receive enable bit in UART0/1\_CON1. The entire receiving process must be performed when the module is enabled.

Receiving data flow: receive data at any time with the reception enable enabled. After receiving the stop bit, set the middle segment and the software clears the interrupt flag.

Currently acceptly data will detect wit, detect receive overflow, frame error, parity error three errors. Software clearance mark required. It is recommended to read the status flag and read the data buf after receiving the receive interrupt. Finally, the received data status flags are cleared.

Data character is started by logic 0, 8 or 9 data bit (LSB send first) and stop bits (1bit) of logic 1. After receiving the stop bit to the shifter, if the receive data shift register is not full (RI0/1=0), data characters are transferred to the receive data register, setting the receive data register full (RI0/1=1) status flag. If the rx\_full\_if of the receive data register is already set at this time, set the

overflow (UART0/1\_RO) status flag, the new data will be lost. Because the receiver is double buffered, after setting rx\_full\_if, program has a full character time for reading before reading the data of the receive data buffer to avoid receiver overflow.

When the program detects that the receive data register is full (RI0/1=1), it acquires data from the receive data register by reading UART0/1\_BUF.

#### 10.1.4. Receiver Sampling Method

The receiver uses with a 16x baud rate clock for sampling. The receiver searches for falling edge on the RXD serial data input pin by extracting the logic level samples at 16x baud rate. The falling edge is defined as the logic 0 level after 3 consecutive logic 1 samples. The 16x baud rate clock is used to divide the bit time into 16 segments, labeled RT1 and RT16 respectively.

The receiver then samples at each bit time of RT8, RT9 and RT10, including the start and stop bits to determine the logic level of the bit. The logic level is the logic level of most samples advanced during the bit time period. When the falling edge is located, the logic level is 0 to ensure that this is the true starting bit, not the noise. If at least two of the three samples are 0, the receiver assumes that it is synchronized with the receiver character. Start shifting to receive the following data, if the above conditions are not met, exit the state machine and return to the waiting for falling edge state.

The falling edge detection logic constantly looks for the falling edge. If an edge is detected, the sample clock resynchronizes the bit time. This improves the reliability of the receiver when noise or mismatch in baud rate occurs.

#### 10.1.5. Multiprocessor Mode

Multiprocessor mode, only works in 9-bit mode, when the received UART0/1\_R8 bit=1, the receive interrupt is set, otherwise it is not set. The role of this mechanism is to eliminate the software overhead of handing unimportant information for different receivers.

In this application system, all receivers estimate the address character (ninth bit=1) of each message. Once it is determined that the information is intended for different receivers, subsequent data characters (ninth bit=0) are not received.

Configuration process: configuring receive enable, configuring multiprocessor mode, received address data (ninth bit=1), receive and generate an interrupt. The application confirms that the addresses match, and the match configures to turn off the multiprocessor mode. All subsequent data (ninth bit=0) can be received and interrupted until the next time the address data is received, the address does not match, then the multiprocessor mode is turned on. Then all subsequent data is not received until the next address data, and then cyclically applied.

## 10.4. UART Configuration Process

UART initial configuration process

UART suggested application process:

1. Configuration module enable, receive enable, mode select: UART0\_CON1;
2. Configure baudrate, open interrupt enable: UART0\_BDL, UART0\_CON2;
3. Write UART0\_BF starts to send data, after detecting the transmission interrupt, clear the interrupt flag TI0;
4. Receive interrupt detected, first read status UART0\_STATE. Then read R8 and UART0\_BUF, finally clear the receive status flag (UART0\_STAT[3:0] = B0000). One receiving process is completed, waiting for the next receiving interrupt;
5. If the configuration interrupt is not enabled, the program executes the UART0 function. Also read the status flag first, then read UART0\_R8 and UART0\_BUF, and finally clear the status flag.
6. Interrupt flag clear operation. In full-duplex operation, clear flag bit operation requires a valid interrupt bit to be written 0, and other interrupt bits to be written as 1 (write 1 as invalid operation), otherwise it is easy to operate incorrectly. For example: when the send interrupt is valid, you need to write UART0\_STATE = 0x0F; (configuration UART0\_STATE[0:3] = 0x0F, UART0\_R8 write is invalid, UART0\_T8 needs to configure valid transmit data when it is in 9

bit mode and does not have parity).

7. 8 bit mode: Parity enable is valid.

9 bit mode: When the parity bit is enabled, when the parity bit calculated by the ninth bit is not enable, the ninth bit is the UART0\_T8 written in. Only send interrupts and receive interrupts. The error flag only marks the error detection of the current data, and only the corresponding bit writes 0 clear, do not jump out of error interrupt. The transmit interrupt is set after the stop bit is sent, and the software clears it. The receive interrupt is set after the stop bit is sent, and the software clears it.

Multiprocessor mode: Only works in 9 bit mode, received UART0\_R8= 1, receive interrupt is set, otherwise it is not set. When using multiprocessor mode, configuring receive enable and multiprocessor mode. Receive address data (the ninth bit=1) and generate an interrupt, confirm that the address matches. Matching configures the multiprocessor mode to be turned off, and all subsequent data (the ninth bit = 0) can be interrupted by the received interrupt, until the next time data is received. If the address do not match, the multiprocessor mode is turned on, and all subsequent data is not received until the next address data.

Hardware response: Send data is opened by the value written to UART0\_BUF. The interrupt flag is sent after the stop bit is sent. The software clears the interrupt flag and waits for the next write. The receive data receives data at any time when the receiving enable is effective. Set receive interrupt after receiving stop bit, software clear interrupt flag. The currently received data has a detection mechanism that can detect three errors of receive overflow, frame error, and parity error. Both require a software clear flag. It is recommended to read the status flag after the receive interrupt and clear the receive status flag UART0\_STATE[0:3].

**Note: The mapping synchronization output function is not supported.**

## 11. PWM

### 11.1. PWM0 Function Description

PWM0 Function Description:

- The clock source is the fixed clock SYS\_CLK\_24M;
- Support up to 4 channels, each channel is individually enabled
- 16bit counter;
- Configurable counting period, adjustable duty cycle of each channel;
- PWM output waveform polarity can be configured;
- Select the output channel through the PWM0\_IO\_SEL register

The PWM0 module supports 4 channels. Each channel can be individually controlled and enabled, sharing a 16-bit counter. The counting clock is 24MHz and the system clock is synchronized. The period of the PWM0 signal is determined by the value of the period configuration register (PWM0\_MOD), the duty cycle is determined by the setting in the channel register (PWM0\_CHn\_CNT), the polarity of the PWM0 signal is determined by the setting in the PWM0\_CH\_CTRL control bit, 0% and 100% Space ratios are all possible.

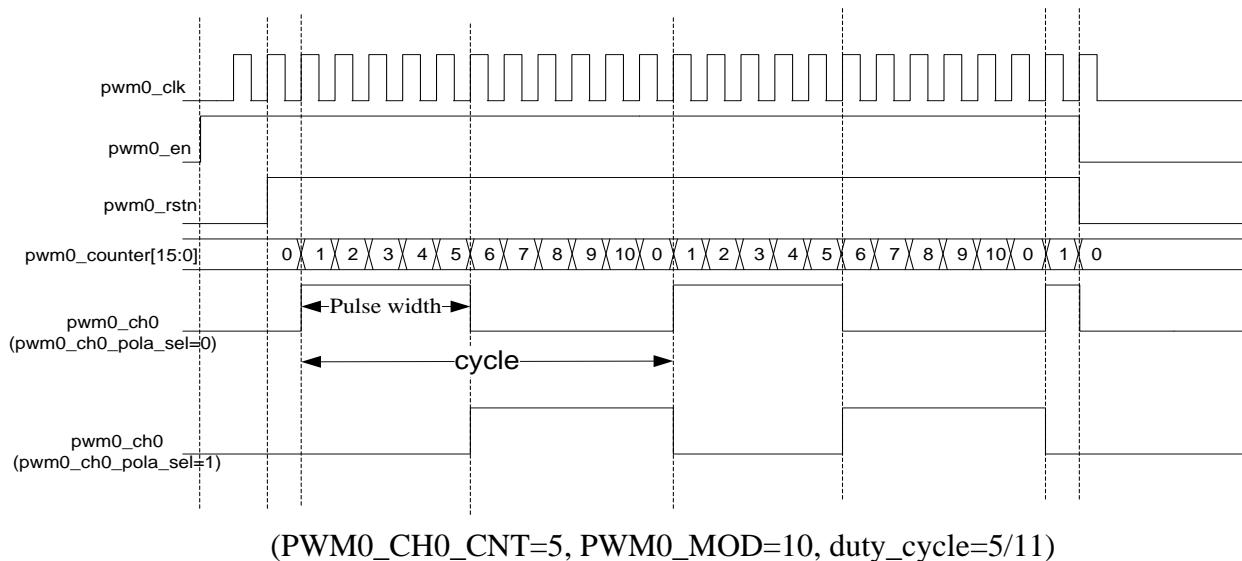

Pulse width = (PWM0\_CHn\_CNT)

Cycle = (PWM0\_MOD+1)

Duty cycle = pulse width/period

PWM0 counter counts up from 0x0000, when PWM0\_CHn\_CNT is counted, the output is inverted. This time is the pulse width. Counting until the count overflows at PWM0\_MOD+1. If PWM0\_CH0\_POLA\_SEL=0, PWM0 signal enters high state when output is flipped. If PWM0\_CH0\_POLA\_SEL=1, PWM0 signal enters high state when output overflows.

When channel count register (PWM0\_CHn\_CNT) is set 0x0000, the duty cycle is 0. When channel count register (PWM0\_CHn\_CNT) is set to a value greater than the value set by the period configuration register (PWM0\_MOD) to achieve a 100% duty cycle. The counter is automatically reloaded and will not stop by itself until the register PWM0 is enabled to stop and the counter is cleared.

## 11.2. PWM1/2 Function Description

PWM1/2 features are as follows:

- ◆ The clock source is the fixed clock SYS\_CLK\_24M;
- ◆ Support 2 channels, each channel is individually enabled;
- ◆ 16-bit counter;
- ◆ Configurable counting period, adjustable duty cycle of each channel;
- ◆ PWM output waveform polarity can be configured

The PWM1/2 module supports 2 channels. Each channel can be individually controlled and enabled, sharing a 16-bit counter. The counting clock is 24MHz and the system clock is synchronized. The period of the PWM1/2 signal is determined by the value of the period configuration register (PWM\_MOD), the duty cycle is determined by the setting in the channel register (PWM\_CHn\_CNT), and the polarity of the PWM signal is determined by the setting in the PWM\_CH\_CTRL control bit, 0% and 100% All duty cycles are possible.

$$\text{Pulse width} = (\text{PWM1/2\_CHn\_CNT})$$

$$\text{Cycle} = (\text{PWM1/2\_MOD}+1)$$

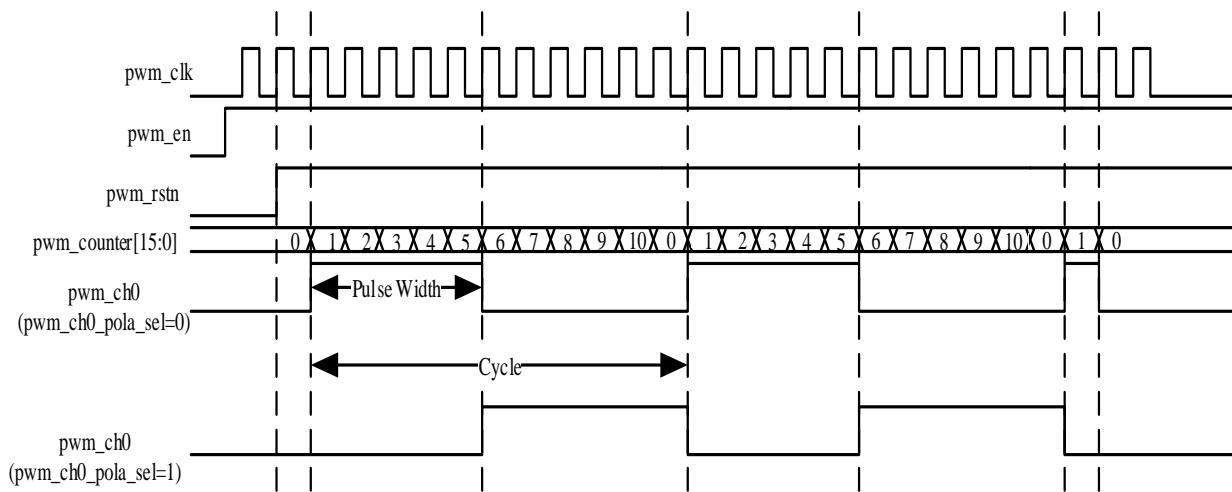

$$\text{Duty cycle} = \text{pulse width}/\text{period}$$

The PWM1/2 counter starts counting up from 0x0000. When PWM1/2\_CHn\_CNT is counted, the output flips. This period of time is the pulse width. Continue counting until the count overflows when PWM1/2\_MOD+1 is counted.

For example: if PWM1\_CH0\_POLA\_SEL=0, the PWM1 signal enters the low state when the output is inverted, and the PWM1 signal enters the high state when the count overflows. If PWM1\_CH0\_POLA\_SEL=1, the PWM1 signal enters the high state when the output is inverted,

and the PWM1 signal enters the low state when the count overflows.

When the channel count register (PWM1/2\_CHn\_CNT) is set to 0x0000, the duty cycle is 0%; when the channel count register (PWM1/2\_CHn\_CNT) is set to be greater than the value set by the period configuration register (PWM1/2\_MOD), it can achieve 100% Duty cycle. The counter is automatically reloaded and will not stop by itself. It will not stop until the PWM1/2 register is enabled and closed, and the counter is cleared. If PWM1/2\_MOD is configured as 0, the waveform outputs 0.

PWM1/2 output waveform

PWM\_CH0\_CNT=5, PWM\_MOD=10, duty\_cycle=5/11

1	PWM1_EN	PWM1 module enable register 1: enable; 0: not enable
0	PWM0_EN	PWM0 module enable register 1: enable; 0: not enable

Module enable register, channel duty cycle and cycle register can be configured only when PWMx\_EN=1 (x=0/1/2). When the cycle register is finally configured, the counter starts counting. When PWMx\_EN=0 is configured, the timing is reset, the count value stops counting, and the PWM waveform output of all channels is 0.

PWM0\_CHx\_CMOD is the duty cycle selection register for configuring channels 1/2/3. PWM0\_CHx\_CMOD = 0 is its own corresponding duty cycle register configuration. When PWM0\_CHx\_CMOD = 1, select the channel 0 duty cycle configuration. This configuration can output the same waveform as the channel 0 duty cycle and cycle. If the polarity configuration is the same as channel 0 On the contrary, a completely complementary waveform can be output.

This register contains channel enable and channel PWM0 output waveform polarity selection configuration, 4 channels are individually enabled, and the polarity of each channel is individually configurable. When CHn\_EN=0, the PWM waveform of the channel is not output (n=0/1/2/3, channel 0/1/2/3). When CHn\_POLA\_SEL=0, the count value is counted to PWM0\_CHn\_CNT when the output is low, and the count overflow output is high. When CHn\_POLA\_SEL=1, the waveform is opposite. When the count value reaches the PWM0\_CHn\_CNT configuration, the output is high, and the count overflow output is low.

PWMX\_CH\_CTRL (C4H) PWMX control register

Bit number	7	6	5	4
Symbol	PWM2_CH1_POLA_SEL	PWM2_CH0_POLA_SEL	PWM2_CH1_EN	PWM2_CH0_EN
R/W	R/W	R/W	R/W	R/W
Reset value	0	0	0	0
Bit number	3	2	1	0
Symbol	PWM1_CH1_POLA_SEL	PWM1_CH0_POLA_SEL	PWM1_CH1_EN	PWM1_CH0_EN
R/W	R/W	R/W	R/W	R/W
Reset value	0	0	0	0

Bit number	Bit symbol	Description
7	PWM2_CH1_POLA_SEL	PWM2 channel 1 polarity selection ch1_pola_sel 1: The count value overflows and the output is low; 0: The count value overflows and the output is high
6	PWM2_CH0_POLA_SEL	PWM2 channel 0 polarity selection ch0_pola_sel 1: The count value overflows and the output is low; 0: The count value overflows and the output is high
5	PWM2_CH1_EN	PWM2 channel 1 enable ch1_en 1: enable; 0: disable
4	PWM2_CH0_EN	PWM2 channel 0 enable ch0_en 1: enable; 0: disable
3	PWM1_CH1_POLA_SEL	PWM1 channel 1 polarity selection ch1_pola_sel 1: The count value overflows and the output is low; 0: The count value overflows and the output is high
2	PWM1_CH0_POLA_SEL	PWM1 channel 0 polarity selection ch0_pola_sel 1: The count value overflows and the output is low; 0: The count value overflows and the output is high

1	PWM1_CH1_EN	PWM1 channel 1 enable ch1_en 1: enable; 0: disable
0	PWM1_CH0_EN	PWM1 channel 0 enable ch1_en 1: enable; 0: disable

This register contains channel enable and channel PWM1/2 output waveform polarity selection configuration, 2 channels are individually enabled, and the polarity of each channel is individually configurable. When CHn\_EN=0, the PWM1/2 waveform of the channel will not be output (n=0/1, channel 0/1). When CHn\_POLA\_SEL=0, the count value will output low when PWM1/2\_CHn\_CNT is configured, and the count overflow will output high. When CHn\_POLA\_SEL=1, the waveform is opposite. When the count value reaches the PWM1/2\_CHn\_CNT configuration, the output is high, and the count overflow output is low.

#### **PWM secondary bus register:**

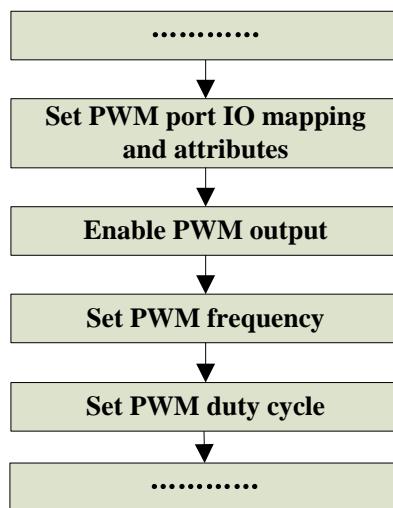

PWM0\_IO\_SEL(2DH) PWM0 port selection register

Bit number	7	6	5	4	3	2	1	0
Symbol					-			
R/W					R/W			
Reset value					0			

Bit number	Bit symbol	Description
3	PWM0_CH3_SEL	PWM0 channel 3 select IO port configuration 0: PB3 port selects PWM0_CH3 function 1: PC5 port selects PWM0_CH3 function
2	PWM0_CH2_SEL	PWM0 channel 3 select IO port configuration 0: PB2 port selects PWM0_CH2 function 1: PC3 port selects PWM0_CH2 function
1	PWM0_CH1_SEL	PWM0 channel 3 select IO port configuration 0: PB1 port selects PWM0_CH1 function 1: PC0 port selects PWM0_CH1 function
0	PWM0_CH0_SEL	PWM0 channel 3 select IO port configuration 0: PB0 port selects PWM0_CH0 function 1: PB5 port selects PWM0_CH0 function

Note: PWM0 has four channels, each channel corresponds to two IO ports, but only one of them is allowed to output at the same time.

## 11.5. PWM Configure Process

PWM configure process

PWM0 configuration process:

1. Configure the channel control register PWM0\_CH\_CTRL (channel enable and polarity selection);
2. Configure the enable register PWM0\_EN, configure the count register PWM0\_CHn\_CNT\_L/H, and the period register PWM0\_MOD\_L/H (the last configuration) to start working.

Note:

1. The period and duty cycle registers need to be configured when PWM0\_EN=1. The counting register PWM0\_CHn\_CNT\_L/H and the period register PWM0\_MOD\_L/H (update the duty cycle and period) are allowed to be configured during operation, and they are allowed to be in the same cycle. Multiple channels are updated at the same time. The channel control register PWM0\_CH\_CTRL is not allowed to be configured during the update period. The channel control register PWM0\_CH\_CTRL can be changed only when PWM0\_EN=0. When PWM0\_EN=1, writing the count register and period configuration register will directly update the duty cycle and period. During the counter operation, the write count register and period configuration register will be latched, and the register value will be updated when the counter (PWM0\_MOD) becomes (PWM0\_MOD+1), that is, the duty cycle and period will be updated after a complete period.
2. The configuration process of PWM1/2 is the same as PWM0.
3. Frequency range: 370 Hz~369 kHz is recommended.

## 12. Touch Key

CSD features:

- CSD charge and discharge clock three modes are optional:
  - Fixed frequency division of the system clock 6M~369k
  - PRS 1.5M normal distribution
  - PRS 1.5M evenly distribution
- CSD count clock 24M, 12M, 6M, 4M is optional;
- Counting width 9-16 bits optional;
- Support asynchronous scanning mode;
- Support wake up in wait mode

The BF7613BMXX-XJLX implements multiple functions through a series of register. The relationship between the capacitance detection related quantity and the SFR value is as follows:

The count value is proportional to RESO, Rb resistance, PULL\_I\_SELA\_H, and inversely proportional to VTH\_SEL. In the case of ensuring complete charge and discharge, it is proportional to the charge and discharge frequency set by PRS\_DIV.

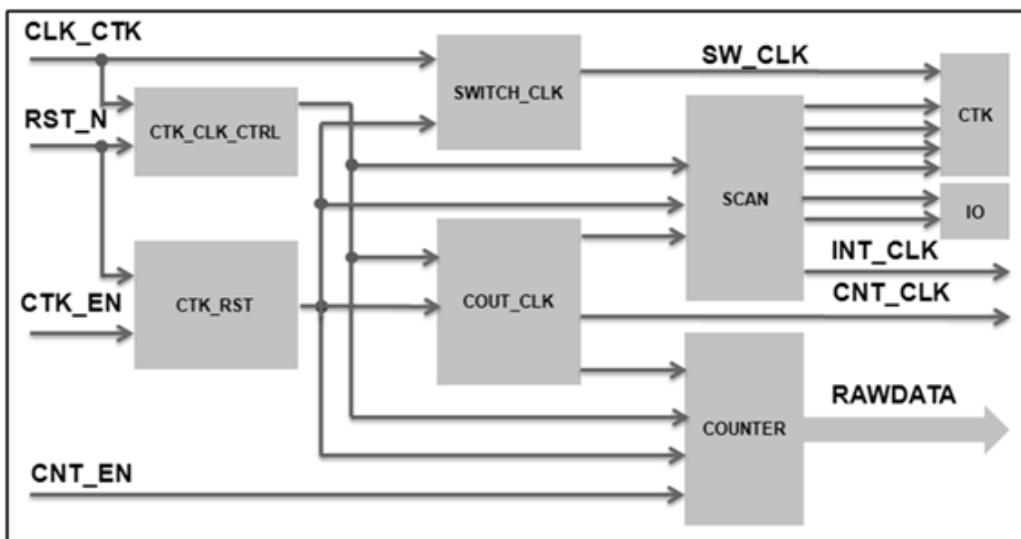

Channel touch variation is proportional to RESO and Rb, and inversely proportional to VTH\_SEL. In the case of ensuring complete charge and discharge. Compared with the charge and discharge frequency set by PRS\_DIV and the amount of touch change.

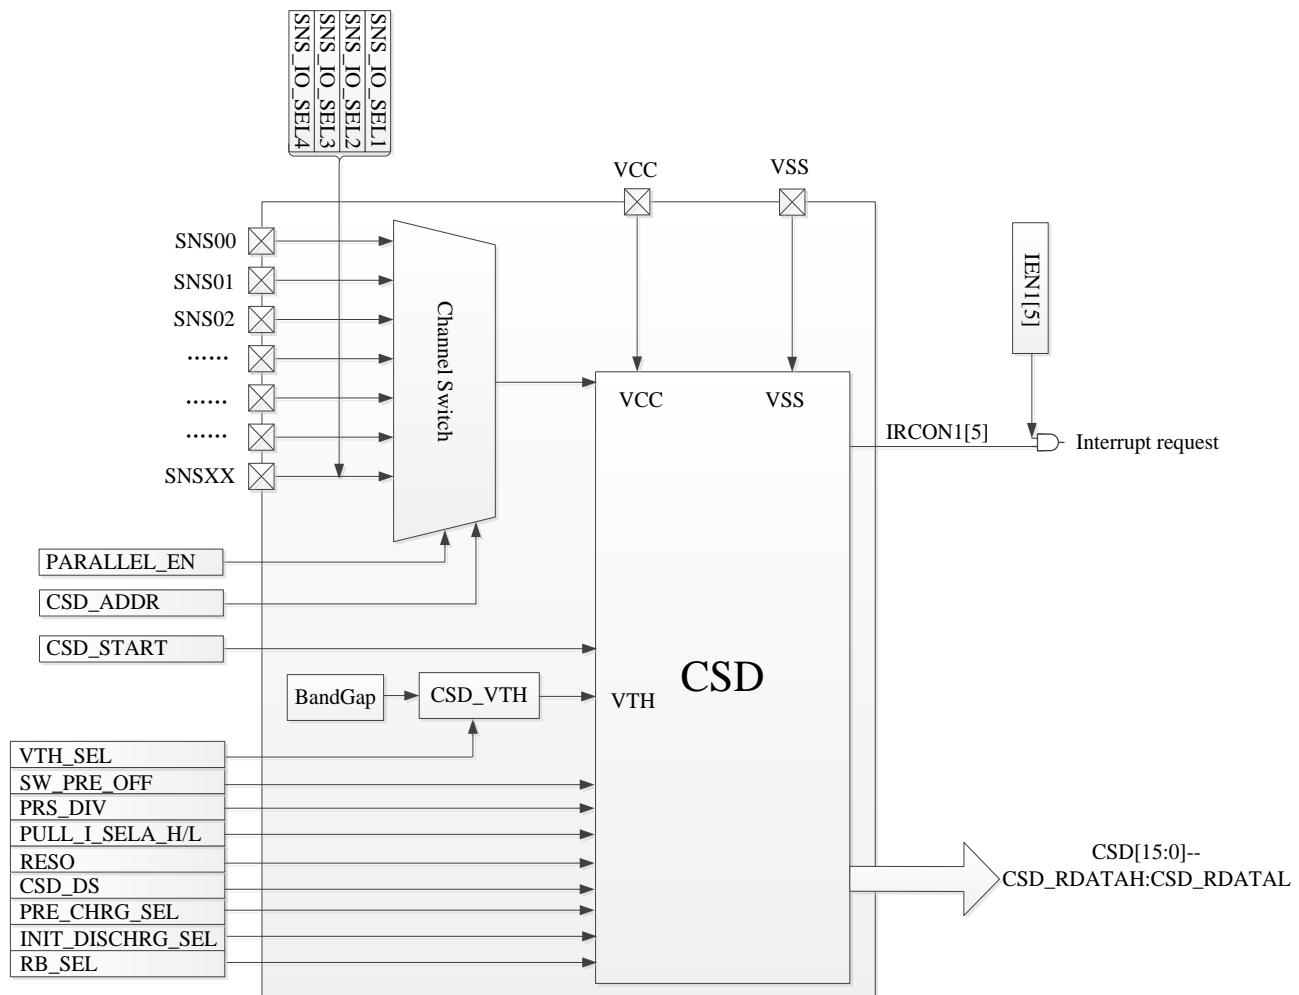

The signal-to-noise ratio of touch is proportional to VTH\_SEL and PULL\_I\_SELA\_L, and inversely proportional to CSD\_DS. When the charge and discharge are incomplete, it is inversely proportional to the charge-discharge frequency set by PRS\_DIV and the signal-to-noise ratio.

The time for a signal touch key detection is related to RESO and CSD\_DS.

**Notes:** When configuring parameters, ensure that the touch key is fully charged and discharged.

## 12.2. Touch Key Register Detailed Description

CSD\_START(CAH) CSD scan open register

Bit number	7	6	5	4	3	2	1	0
Symbol	-	-	-	-	-	-	-	-
R/W	-	-	-	-	-	-	-	R/W
Reset value	-	-	-	-	-	-	-	0

Bit number	Bit symbol	Description
0	--	1: CSD scanning is on;0: CSD scan stops Write 1 in CSD_START to start scanning. After one scan, the hardware will automatically set to 0. If you want to start the next scan, you need to set it to 1 again by software; if CSD_START=0 during the scan, the scan will stop immediately, and the module will have related internal signals Reset

		Note: Must be used in accordance with the process configuration: CSD_START=1, if interruption is detected, configure CSD_START=0. CSD_START is not allowed to be configured during scanning

### 12.3. Touch Key Configure Process

CTK touch key scan for query or interrupt mode. At first, configuring the CTK scanning parameter. Second, starting CTK scanning; Then obtain and save CTK data at CTK interrupt, software algorithm for data processing and touch key output judgement.

CTK configure process

Through the sensitivity parameter configuration, a set of parameters with better signal-to-noise ratio is obtained, thereby improving the accuracy of the key judgment.

1. **RESO:** 0~7 CTK capacitance scanning resolution, counter digits: **(RESO + 9)bit**, the bigger CTK scanning resolution, the bigger the downward rawdata, the noise is increased at the same time, conversely reverse.
2. **VTH\_SEL:** 0~7, the lower VTH, the bigger raw data, the noise is increased at the same time, conversely reverse.
3. **CSD\_DS:** Detect speed **0: 24M, 1: 12M, 2: 6M, 3: 4M**, the slower detect speed the slower raw data simple time, conversely reverse. Suggest default 24M, at least twice the speed of the PRS clock.
4. **RB\_SEL:** Rb resistance select: **4: 60k, 5: 80k**; The greater resistance, the bigger raw data, the noise is increased at the same time, conversely reverse.
5. **PRS\_DIV:** front-end charge and discharge clock frequency selection register:
  - a) 0 ~61: fixed frequency:  $F=F48M/2/(PRS\_DIV+4)$  (6M~369K);
  - b) 62: the highest frequency 3M, the lowest frequency 1M, center frequency 1.5M, normal distribution;
  - c) 63: the highest frequency 3M, the lowest frequency 1M, center frequency 1.5M, evenly distributed;
  - d) The larger the PRS clock, the larger the amount of charge in Rawdata, and the greater the noise introduced, and vice versa.
6. **PULL\_I\_SELA\_L:** pull-up current source low 8 bit.
7. **PULL\_I\_SELA\_H:** pull-up current source high bit, default: 0x01.
  - a) Current resources value = $255.5-0.5*\{PULL\_I\_SELA\_H, PULL\_I\_SELA\}$ , the smaller the current source, the smaller the count value, default: 0x00.

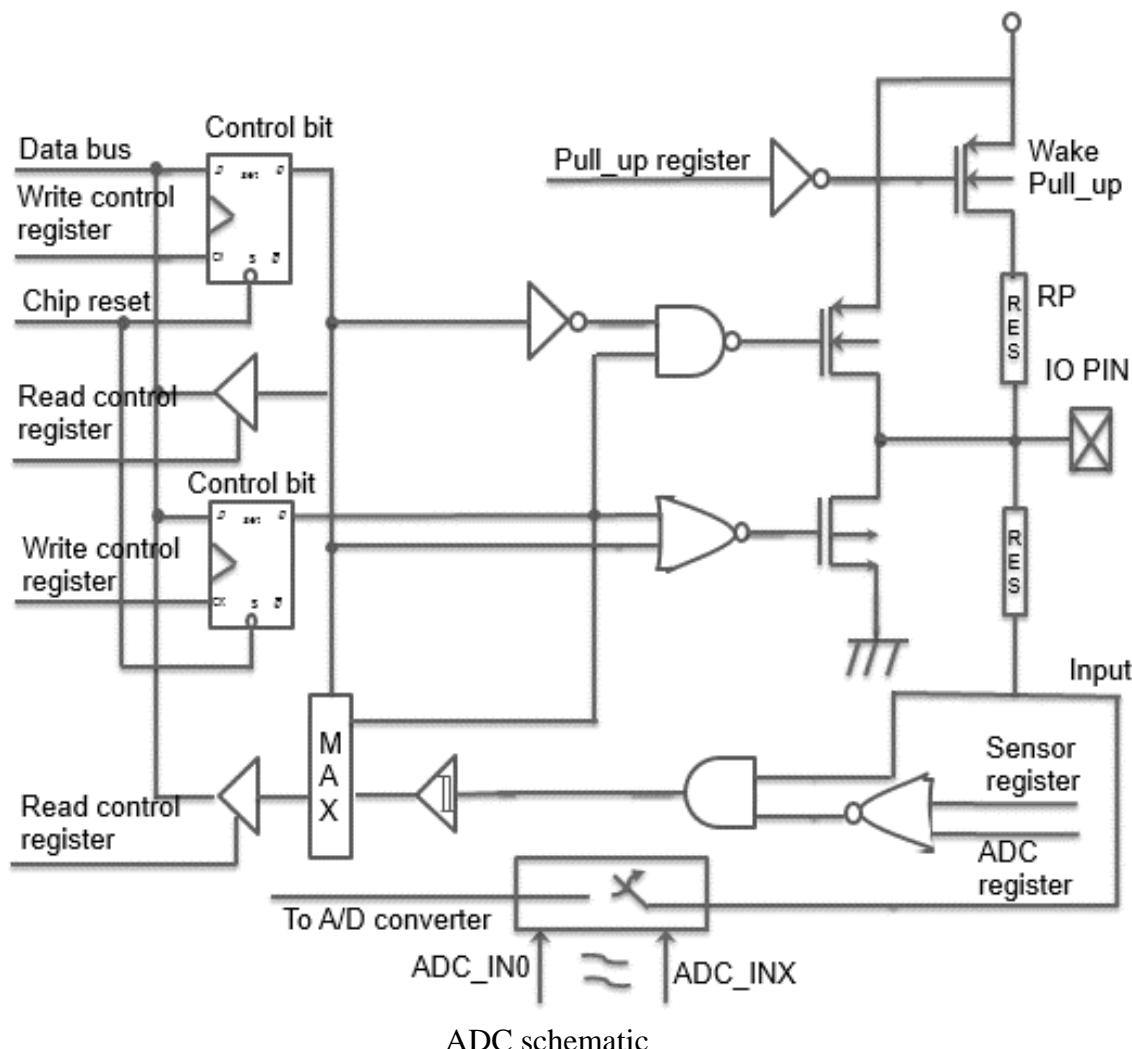

**Notes:**

1. **Rawdata is the real-time raw count value of the CTK capacitor counter.**
2. **In practical applications, it is necessary to view the data through the programming software and compare the parameters with good signal-to-noise ratio.**
3. **Chip supply voltage and reference voltage:  $VCC-VTH>0.5V$ .**

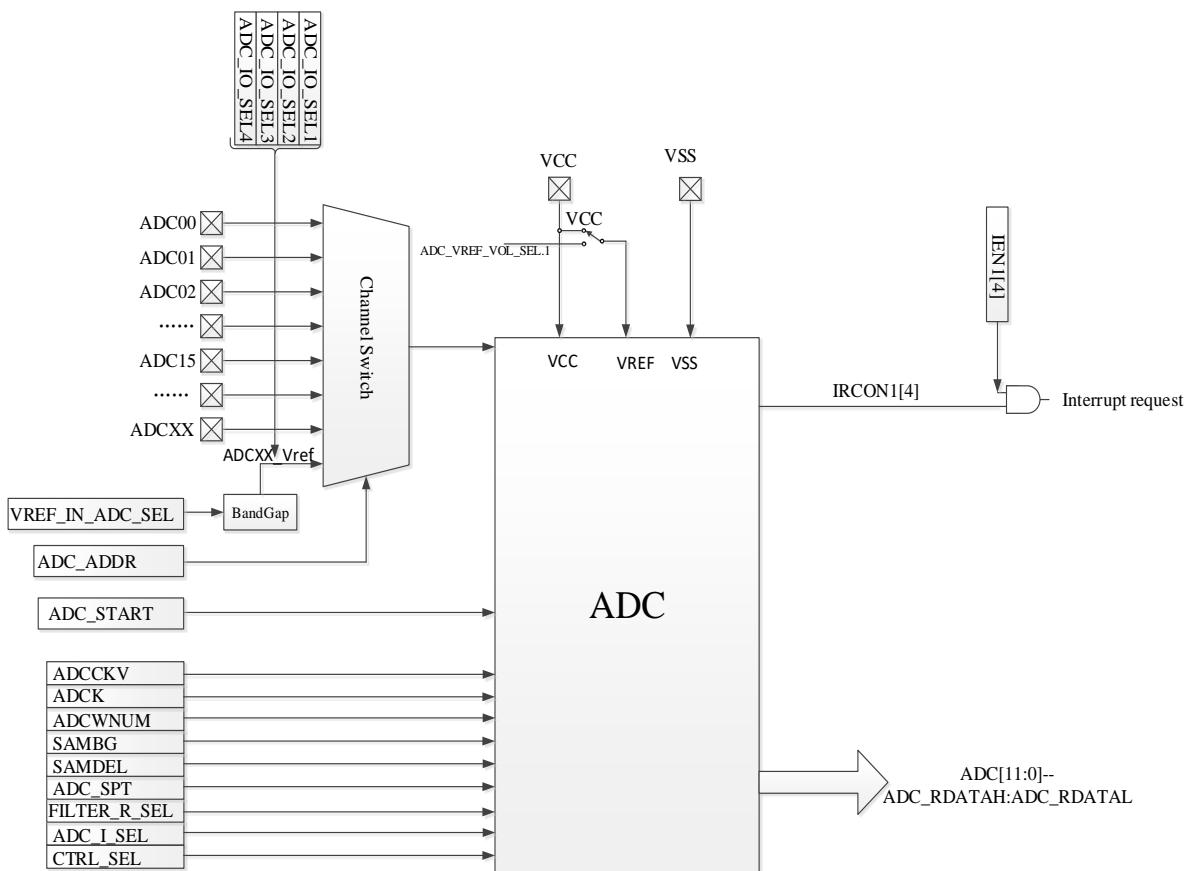

## 13. ADC

The BF7613BMXX-XJLX chip include a signal-ended, 12-bit linear successive approximation analog -to-digital converter (ADC). The reference voltage of the ADC is connected to the VCC of the chip. ADC channels can input independent analog signals. ADC module converts one channel at a time, ADC\_START=0→1(↑) turn on conversion. Update the ADC result register and generate an interrupt after the conversion is complete. The ADC module has the following characteristics:

- Liner successive approximation ADC with 12bit resolution;
- Single conversion mode;
- Sampling time and conversion speed are configurable;
- Support wake up in wait mode

$T_{W1}=(ADCWNUM+3+ SAMDEL)*T_{adc\_clk}$	Distance conversion interval after sampling is completed and delay time
$T_{W2}=(2*1+12)*T_{adc\_clk}$	Fixed time

- Timing requirements:  $(3+ADCWNUM)/F\_ADCK > 4 /F\_ADCCKV$ ;  
 $F\_ADCK$ : ADC frequency division clock;  
 $F\_ADCCKV$ : ADC comparator offset cancellation analog input clock;  
 ADC external signal plus RC filtered voltage setting time  $\geq 2 * (\text{ADC sampling converts time})$ ;
- When selecting VCC as the ADC reference voltage**, when the power supply voltage fluctuates greatly or drops, the VCC voltage value can be inversely calculated by the formula  $\text{ADCINNER\_Data} / \text{VREF\_IN\_ADC\_SEL} = 4096 / \text{VCC}$ . The voltage value of Vin can be inversely calculated by the formula  $\text{Vin\_Data} / \text{Vin} = 4096 / \text{VCC}$ .  
 $\text{ADCINNER\_Data}$ : ADC internal channel data;  
 $\text{Vin\_Data}$ : ADC input channel data;  
 $\text{Vin}$ : input voltage;  
 $\text{VREF\_IN\_ADC\_SEL}$ : Need to read the chip calibration value,  $\text{Vin} = (\text{Vin\_Data}/\text{ADCINNER\_Data}) * \text{VREF\_IN\_ADC\_SEL}$ .  $\text{VREF\_IN\_ADC\_SEL}$  needs to read the chip calibration value, first obtain the internal channel data, and then obtain the input voltage  $\text{Vin\_Data}$  data, and the time between two data acquisitions should be as short as possible;  
**When selecting ADC\_VREF\_VOL\_SEL 4V reference voltage, it is recommended to use 3MHz for ADC frequency division clock.** Through the formula  $\text{Vin\_Data}/\text{Vin} = 4096/\text{ADC\_VREF\_VOL\_SEL}$ , the Vin voltage value can be inversely

calculated

Vin\_Data: ADC input channel data;

Vin: input voltage (0~ADC\_VREF\_VOL\_SEL);

VREF\_IN\_ADC\_SEL: Need to read the chip calibration value,

$Vin = (Vin\_Data/ADCINNER\_Data)*VREF\_IN\_ADC\_SEL$ , ADC\_VREF\_VOL\_SEL needs to read the calibration value of the chip, first obtain the internal channel data, and then obtain the input voltage Vin\_Data data, the time between obtaining the data should be as short as possible;

3. ADC interrupt conditions: the configuration sequence is ADC\_IO\_SEL enable -> ADC interrupt enable -> ADC\_ADDR (the address must correspond to ADC\_IO\_SEL) -> ADC\_START. Pay attention to the initial configuration timing during application. If there is an application where the ADC and IO port functions are multiplexed, you need to pay attention to the switching timing. If the ADC\_IO\_SEL enable is turned off or the address does not correspond to ADC\_IO\_SEL, the ADC scan cannot be turned on. The configuration sequence must be followed: ADC\_IO\_SEL enable -> ADC interrupt enable -> ADC\_ADDR (the address must correspond to ADC\_IO\_SEL) -> ADC\_START sequence to start ADC scanning.

## 14. LVDT

The BF7613BMXX-XJLX supports low pressure alarm function, effectively monitor voltage dynamics. Support 7 levels of voltage: 2.4V/2.7V/3.0V/3.3V/3.6V/3.9V/4.2V (Preset point buck interrupt, hysteresis 0.1V to generate corresponding boost interrupt).

When the voltage monitoring configures the above threshold, the voltage drops to this threshold will trigger a low voltage interrupt. The system can be propely processed in low voltage interrupts according to the needs of the application.

## 15. LED

Features of LED dot matrix drive mode:

- ◆ Supports up to 64 LED drivers, configurable selection matrix 4x4, 4x5, 5x6, 6x7, 7x7, 7x8, 8x8 (pins are fixed after configuration);
- ◆ The scanning sequence of LED0~LED8 can be configured,  $n*(n-1)$  or  $(n-1)*(n-1)$  matrix output (n is the number of pins, n= 5~9)
- ◆ Dual lamps are turned on at the same time, the specific distribution is shown in the matrix description below;
- ◆ Single lamp on-time setting file: 8-bit register, configurable range is 16us-4.096ms, step is 16us;
- ◆ Each lamp driving time is individually selectable;
- ◆ The IO ports have multiple multiplexing relationships. Each IO port needs to be configured by software to switch to LED port. According to the LED matrix mode selection, the LED function of LED0~LED8 corresponding to the IO port is automatically turned on. Each LED port supports PB0~PB7, PC0 select;
- ◆ The address of the 64 lamp matrix is unique, see the matrix description below, which is used to input switch lamp information;
- ◆ Supports high current drive function of 8 GPIO ports.

The scan mode is configurable. The software controls the LED scan to be turned on. The interrupt mode scans once interrupted and stopped. The cycle mode automatically starts to scan the next frame after the scan is completed. If there is no interruption, the software needs to turn off the scan enable.

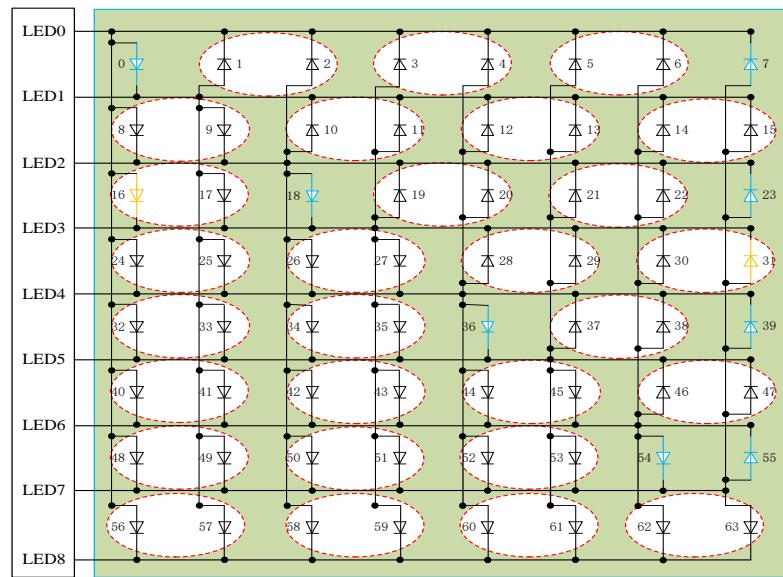

### 15.1. Function Description

LED dot matrix driver circuit consists of a controller, two counter, a comparator and a SRAM memory circuit.

LED dot matrix is a universal 8\*8 matrix dual lamp mode scan, that is, two lights at a time (common cathode).

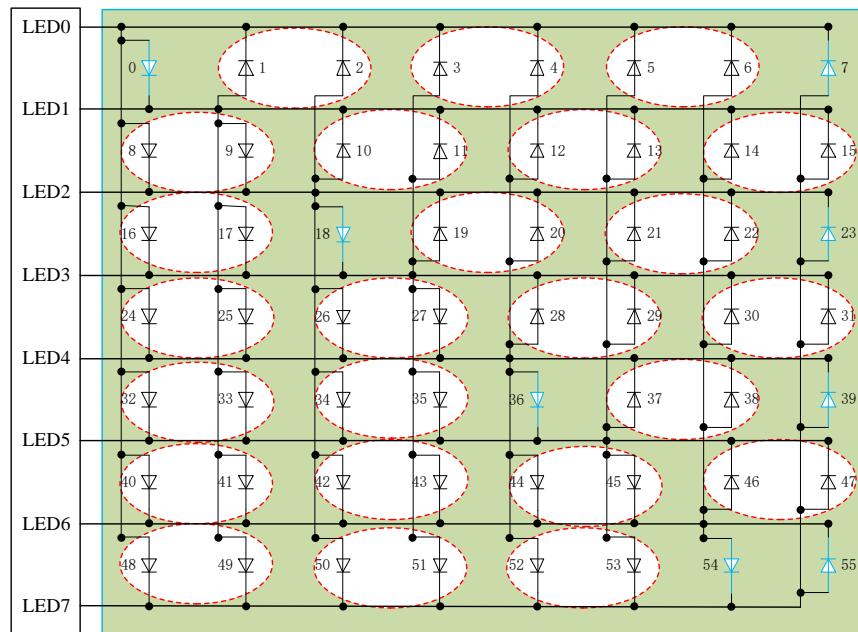

Corresponding to the LED0~LED8 port, up to  $8 \times 8 = 64$  lights can be configured. The lights address of the corresponding position is marked in the 8\*8 dot matrix below. The display configuration in the SRAM corresponding address lighting situation (1 means light, 0 means no light), The hardware code needs to resolve the lighting address and the current scanning address to automatically complete the corresponding IO port output control. Configurable dot matrix 4x4, 4x5, 5x6, 6x7, 7x7, 7x8, 8x8, lamp addresses corresponding to different size lattices are unchanged.

## 16. EEPROM

EEPROM size is 1K Bytes, which can be divided into 2 pages, each page is 512 Bytes, and its address is (0x8400~0x87FF). Page erasure is required when using, then perform byte write operation, and can only be written once after erasing.

EEPROM address

NVR3: When SPROG\_ADDR\_H[2] = 0,

{SPROG\_ADDR\_H[0], SPROG\_ADDR\_L[7:0]}: The logical address (0~511) corresponds to the physical address (0x8400~0x85FF).

NVR4: When SPROG\_ADDR\_H[2] = 1,

{SPROG\_ADDR\_H[0], SPROG\_ADDR\_L[7:0]}: The logical address (0~511) corresponds to the physical address (0x8600~0x87FF).

The following table shows the physical location of 2 BLOCKs of EEPROM:

EEPROM	BLOCK first address	Description
BLOCK0	0x8400	Choose NVR3 and NVR4 as EEPROM, each block size is 512 Bytes, once erasing, erase 512 Bytes space.
BLOCK1	0x8600	SPROG_ADDR_H[2]=1, select block1; SPROG_ADDR_H[2]=0, select block0; SPROG_ADDR_H[0] and SPROG_ADDR_L[7:0] select the address in the page SPROG_ADDR_H[1] is invalid

### 16.3. Page Erase Step

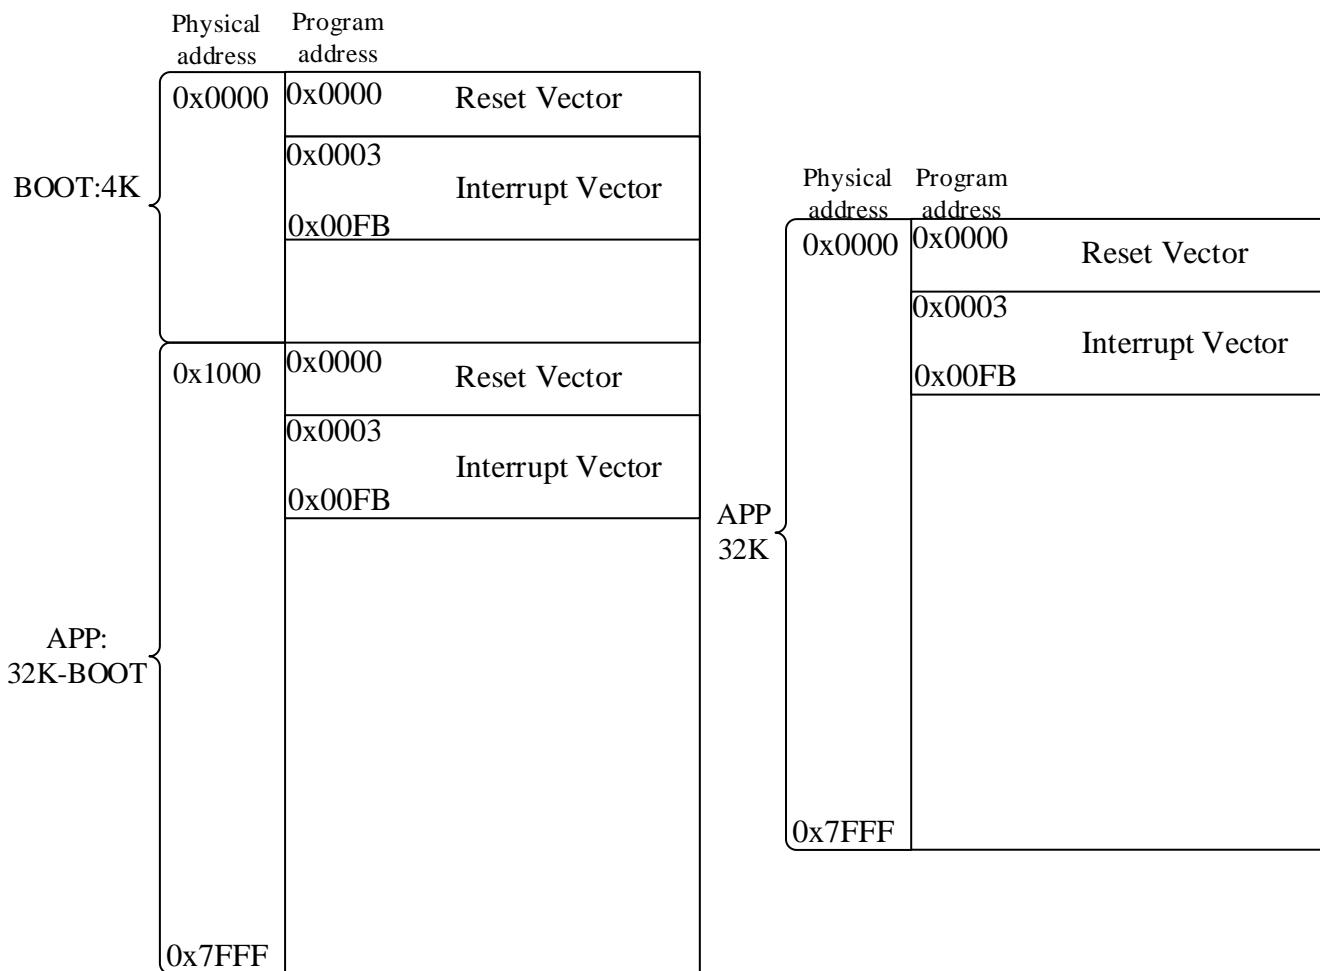

1. SPROG\_TIM[4:0] = 0~9 (5ms recommended), the byte write time is fixed at 23.5us, and it is only configured once in the main program main() function initialization;
2. Turn off the interrupt;
3. Configure SPROG\_ADDR\_L = 0x00;
4. Configure SPROG\_ADDR\_H = 0x0x (select block0), select the page to be erased;
5. Configure SPROG\_CMD = 0x96;
6. Write 4 NOP instructions;
7. Start erasing, the CPU turns off the clock F\_sys\_clk, and turns on the clock F\_sys\_clk after erasing is completed;
8. Need to continue to erase data, skip to step 2;
9. Configure SPROG\_ADDR\_H=0x00 and SPROG\_ADDR\_L=0x00 to restore interrupt settings.

### 16.4. Byte Write Step

1. SPROG\_TIM[4:0] = 0~9 (5ms recommended), the byte write time is fixed at 23.5us, and it is only configured once in the main program main() function initialization;
2. Turn off the interrupt;
3. Configure SPROG\_ADDR\_L, SPROG\_ADDR\_H, select the address of the programming byte;
4. Configure SPROG\_DATA;
5. Configure SPROG\_CMD = 0x69;
6. Write 4 NOP instructions;
7. Start writing, the CPU turns off the clock F\_sys\_clk, and turns on the clock F\_sys\_clk after completion;
8. Need to continue programming data, skip to step 2;
9. Configure SPROG\_ADDR\_H=0x00 and SPROG\_ADDR\_L=0x00 to restore interrupt settings.

## 17. IAP Operation

Flash supports the IAP BOOT upgrade function, and realizes the jump between the BOOT area and the APP area by sending IAP operation commands. The BOOT has its own storage and write protection, and the size of the BOOT area is 4K.

Left: BOOT and APP partition map; Right: APP area without BOOT map

### 17.3. Flash IAP Operation Process

### 17.3.1. Flash IAP Erase Step

In Flash\_BOOT upgrade mode:

1. SPROG\_TIM[4:0] = 0~9 (5ms recommended), the byte write time is fixed at 23.5us, and it is only configured once in the main program main() function initialization;
2. Turn off the interrupt;
3. Configure SPROG\_ADDR\_L = 0x00;
4. Configure SPROG\_ADDR\_H[7:1] and choose to erase the page;
5. Configure SPROG\_CMD = 0x96;
6. Write 4 NOP instructions;
7. Start erasing, the CPU turns off the clock F\_sys\_clk, and turns on the clock F\_sys\_clk after erasing is completed;
8. Need to continue to erase data, skip to step 2;
9. Configure SPROG\_ADDR\_H=0x00 and SPROG\_ADDR\_L=0x00 to restore interrupt settings.

### 17.3.2. Flash IAP Byte Write Step

In Flash\_BOOT upgrade mode:

1. SPROG\_TIM[4:0] = 0~9 (5ms recommended), the byte write time is fixed at 23.5us, and it is only configured once in the main program main() function initialization;
2. Turn off the interrupt;
3. Configure SPROG\_ADDR\_L, SPROG\_ADDR\_H, select the address of the programming byte;
4. Configure SPROG\_DATA;
5. Configure SPROG\_CMD = 0x69;
6. Write 4 NOP instructions;
7. Start writing, the CPU turns off the clock F\_sys\_clk, and turns on the clock F\_sys\_clk after completion;
8. Need to continue programming data, skip to step 2;
9. Configure SPROG\_ADDR\_H=0x00 and SPROG\_ADDR\_L=0x00 to restore interrupt settings.

### 17.3.3. Flash IAP Operation Instruction

Instruction	Instruction response status	Instruction data
Enter upgrade mode instruction	FLASH_BOOT_EN = 1	0x12, 0x34, 0x56, 0x78, 0x9A
Exit upgrade mode instruction	FLASH_BOOT_EN = 0	0xFE, 0xDC, 0xBA, 0x98, 0x76
Enter the APP area instruction	ROM_OFFSETH/L	0xFF, 0x00, 0x88, 0x55, 0xAA
Enter the BOOT area instruction	ROM_OFFSETH/L	0x37, 0xC8, 0x42, 0x9A, 0x65

Instructions for operation:

1. Enter upgrade mode instruction: SPROG\_CMD sequential write: 0x12, 0x34, 0x56, 0x78, 0x9A;
2. Exit upgrade mode instruction: SPROG\_CMD sequential write: 0xFE, 0xDC, 0xBA, 0x98, 0x76;
3. Enter the APP area instruction: BOOT\_CMD sequential write: 0xFF, 0x00, 0x88, 0x55, 0xAA;
4. Enter the BOOT area instruction: BOOT\_CMD sequential write: 0x37, 0xC8, 0x42, 0x9A, 0x65;

Instructions response status:

FLASH\_BOOT\_EN = 1: Indicates that it has entered Flash BOOT upgrade mode,  
FLASH\_BOOT\_EN = 0: Indicates that the Flash BOOT upgrade mode has been exited,  
ROM\_OFFSETH/L address offset status:

CFG\_BOOT\_SEL = 1, ROM\_OFFSETH/L = 0x1000,

If you are currently in the boot area:

CFG\_BOOT\_SEL = 0, ROM\_OFFSETH/L = 0x0000.

Physical address of program execution = PC + ROM\_OFFSETH/L.

Precautions:

1. When writing SPROG\_CMD, BOOT\_CMD instruction data, it must be written in order, otherwise it needs to be written again.
2. The working voltage of MCU is 2.5V~5.5V, and the MCU may work abnormally at 1.5V~2.5V, resulting in abnormal update and misoperation. Therefore, it is recommended not to perform IAP operation when the ADC or LVDT detection voltage is lower than 2.5 V before IAP operation .
3. It is recommended to shield the interrupt during the update process to ensure that the IAP operation will not be affected by the interruption, and resume the interruption after the IAP operation is completed, and perform data verification after updating the data to ensure that the data is updated correctly.

Note:

1. Byte write physical address corresponding register: {SPROG\_ADDR\_H[7:0], SPROG\_ADDR\_L[7:0]};
2. 512Bytes per Block;
3. When operating the 4K Block where the BOOT is located, the BOOT is write-protected and the operation is invalid;
4. When the BOOT function is used, all CODE areas of the program need to subtract the offset address of ROM\_OFFSET\_H/L (PC-ROM\_OFFSET) to access the absolute address of the CODE area.

## 18. Burning and Debugging

### 18.1. SWE Circuit Connection

Two-wire programming and single-wire debugging. When performing simulation debugging, you need to connect a SWE wire. In the SWE debugging mode, the IO function of the SWE port is blocked. It is recommended not to configure other functions of the SWE debugging I/O port to avoid affecting the SWE debugging function.

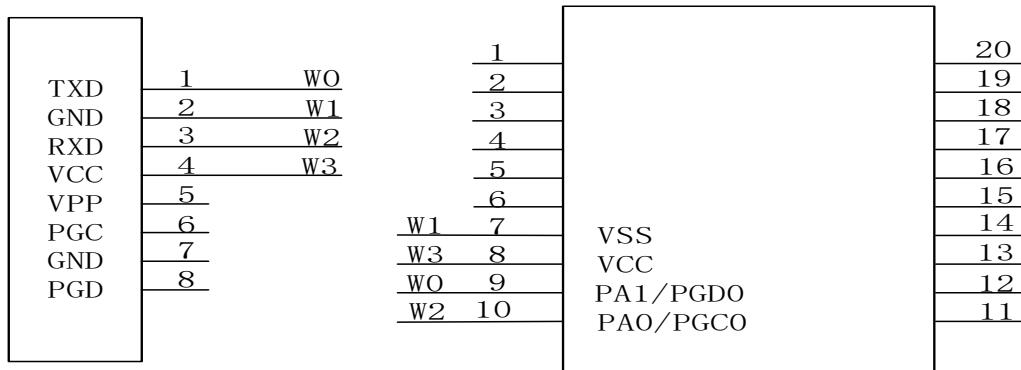

## 18.2. TouchKey Programming

Connect the chip PGD, PGC, VCC, VSS four lines. When entering the programming interface, select the chip of the corresponding model. Open the compiled HEX file, click on a built-in flash to wait for burning.

When entering the debugging interface, first burn the HEX file with the debug data transmission mode, click to open the debug to view the touch key data.

For example:

## 19. CPU Instruction System

### 19.1. Instruction Code

The BF7613BMXX-XJLX instructions are divided into signal-byte instructions, double-byte instructions and three-byte instructions.

Signal-byte instructions: A signal-byte instruction consists of 8 bit binary code. There are only instruction opcodes in the instruction, no instruction operand or instruction operand is implied in the instruction opcode. There are 49 such instructions.

Double-byte instructions: Consists of two bytes, one for opcode and the other for the operand (or operand address), stored in order in program memory. There are 46 such instructions.

Three-byte instructions: Consists of one byte of instruction opcode and two bytes of operands (or operand address). There are 16 such instructions.

### 19.2. Instruction Set

In order to describe the instructions conveniently, some symbols are used in the instructions. The meanings of these symbols are as follows:

addr 11	Lower 11 address
addr 16	16-bit address
direct	Direct addressing, 8-bit internal data and address (including special function registers)
bit	Bit address
#data	8-bit immediate
#data16	16-bit immediate
rel	Signed 8-bit relative displacement
n	Number 0~7
Rn	R0~R7 working registers of the current register group
i	Numbers 0, 1
Ri	Working register R0, R1
@	Register indirect addressing
←	Data transfer direction
∧	Logical "and"
∨	Logical OR
⊕	Logical "exclusive OR"
√	Affect the flag
×	No effect on the flag

CPU instruction symbol meaning table

The assembly instructions used, the function of each instruction, the number of bytes occupied, the instruction execution cycle and the impact on the corresponding flag bit are shown in the following table:

#### 8 bit data transfer instruction

Mnemonic		Function	Impact on the flag				Number of bytes	Number of cycles

#### Pseudo-instruction

Mnemonic	Instruction format	Function description
ORG	【tab:】 ORG addr16	Define the first address of tab
EQU	tab EQU data/tab	Assign values to labels
DB	【tab:】 DB item or item tabel	Define a-byte or multi-byte
DW	【tab:】 DW item or item tabel	16 bit word content used to define two or more cells in memory
DS	【tab:】 DS expression	Specifies to leave several memory cells starting with the label
BIT	tab BIT address	Assign a bit address to a label
END	END is placed at the end of the assembly language program to tell the assembler that the source program ends here.

## 20. Reference Application Circuits

### 20.1. BF7613BM20-SJLX/TJLX Reference Circuit

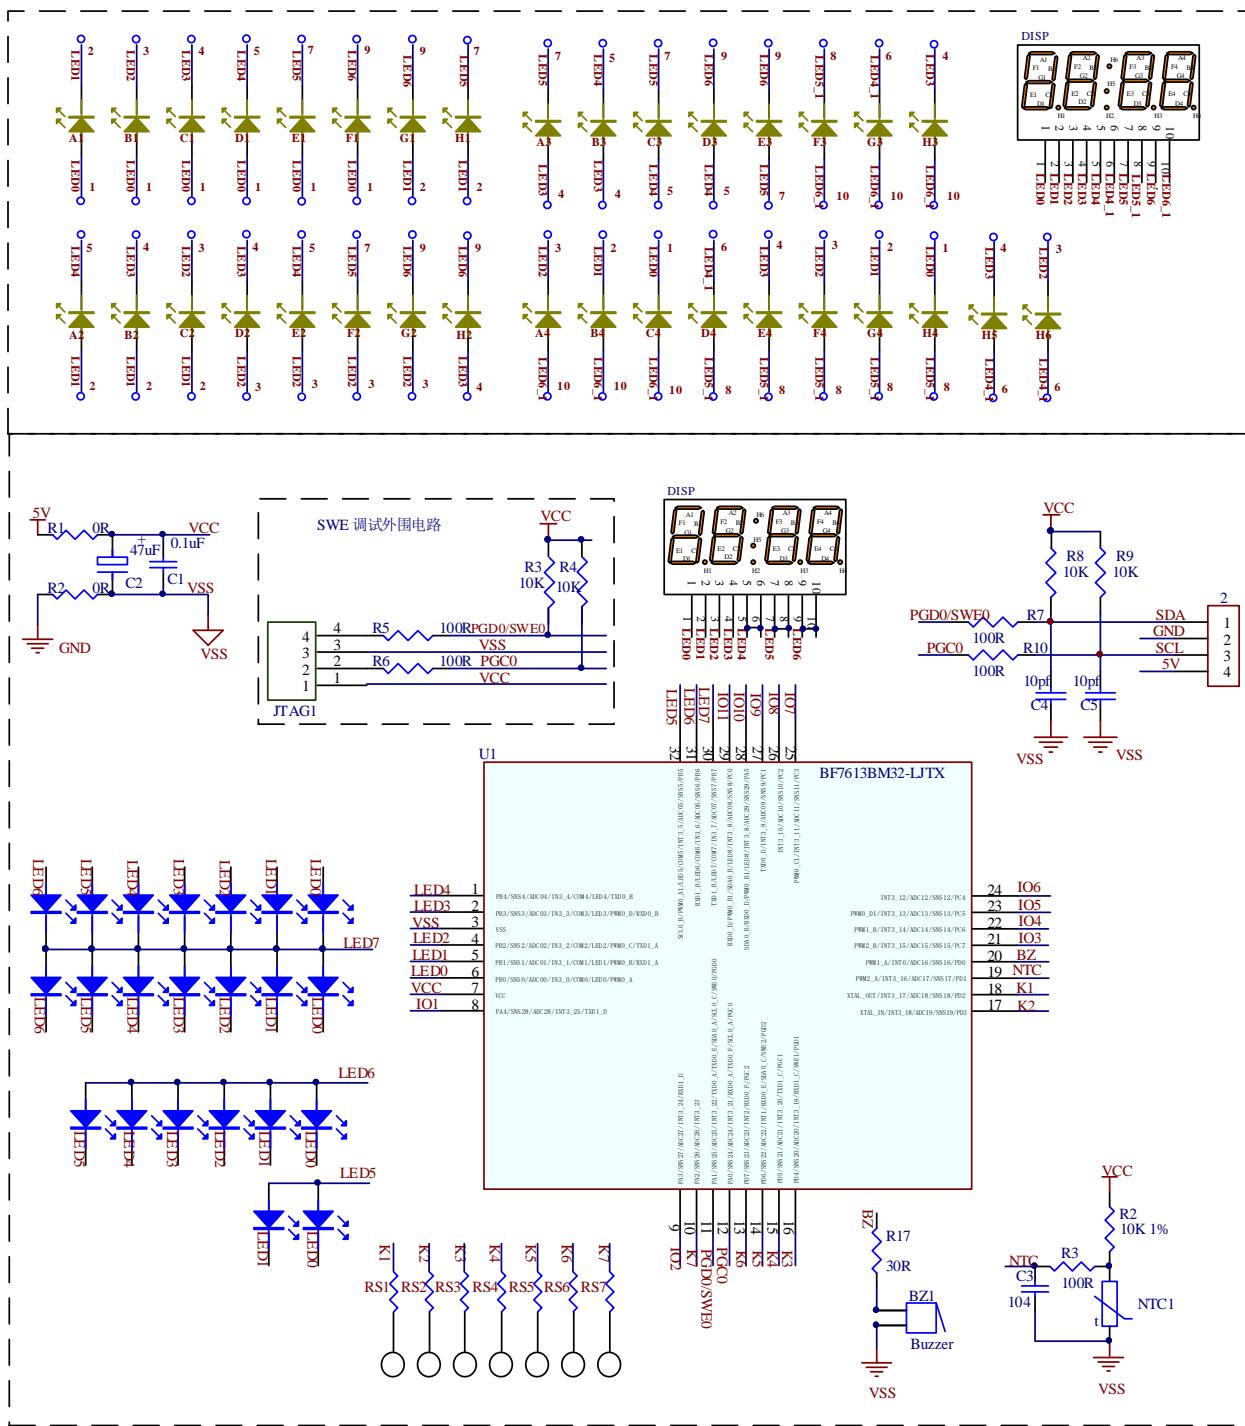

## 20.2. BF7613BM28-SJLX/TJLX Reference Circuit

### 20.3. BF7613BM32-LJTX Reference Circuit

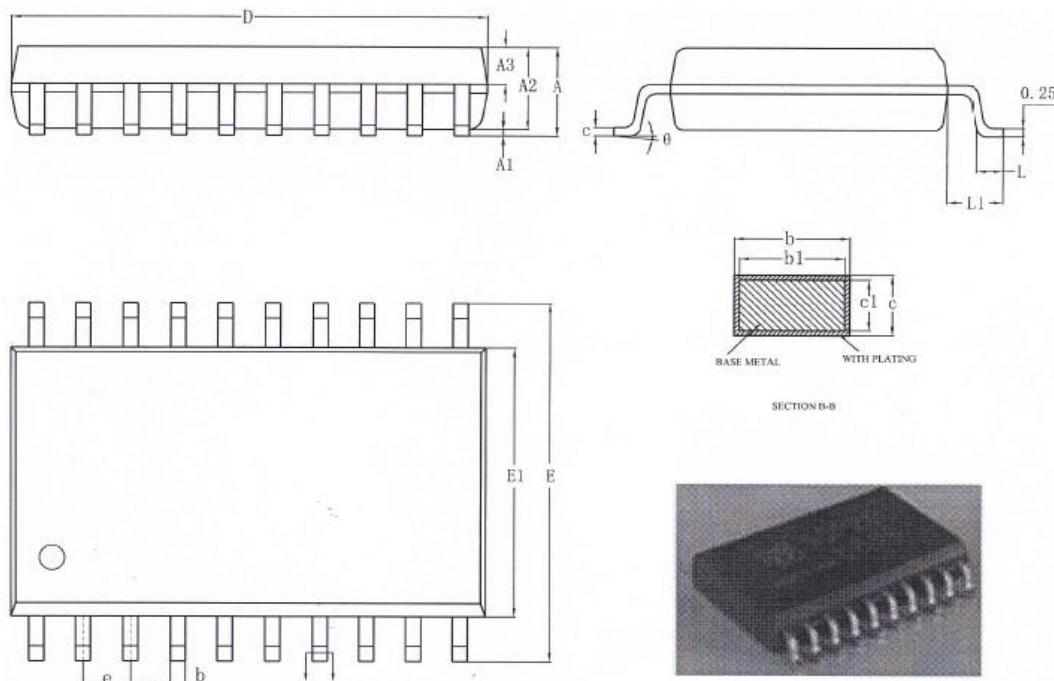

Note: The above reference schematic reference circuit is for reference design only.

1. The RSX channel resistance is recommended to be 1K~8.2K, normal 4.7K.
2. The SWE debugging peripheral circuit is only used for SWE debugging. If the emulator or adapter board has a pull-up resistor, there is no need to connect the SWE pull-up resistor.
3. Replace the 0Ω resistors with parallel power and ground with magnetic beads. The EMI test item (RE) can increase the test margin. The recommended parameter is 600 Ω@100MHz.

2. BYD Semiconductor Co., Ltd. will do its utmost to ensure the high quality and high stability of the company's products. Nonetheless, due to the inherent characteristics of general semiconductor devices such as electrical sensitivity and vulnerability to external physical damage, our products may malfunction or fail under these circumstances. When using our company's products, users are responsible for designing a safe and stable system environment in compliance with safety rules. Users can avoid possible accidents, fires and public injuries by removing redundant devices, failure prevention and fire prevention measures. When the user uses the product, please follow the operating steps specified in the company's latest manual to use the product.
3. The products of BYD Semiconductor Co., Ltd. in this document are designed for general electrical applications (computers, personal tools, company tools, measuring tools, industrial mechanical devices, household appliances, etc.). The company's products can not be used in some special equipment that requires extremely high stability and quality, so as to avoid accidents such as casualties. The range of products that cannot be applied includes atomic energy control equipment, aircraft and aviation devices, transportation equipment, traffic signal equipment, combustion control equipment, medical equipment, and all safety equipment. The company shall not be responsible for any loss or injury caused by users who use it within the non-product application ranges listed above.
